Patents Act 1990

624087

REQUEST FOR A STANDARD PATENT

AND NOTICE OF ENTITLEMENT

The Applicant identified below requests the grant of a patent to the nominated person identified below for an invention described in the accompanying standard complete patent specification.

[70,71] Applicant and Nominated Person:

JOHN C. HARVEY of 333 East 57th Street, New York, NY 10022,  
United States of America.

[54] Invention Title:

SIGNAL PROCESSING APPARATUS AND METHODS

[72] Actual Inventor:

John C. Harvey	James W. Cuddihy
333 East 57th Street	523 East 14th Street,
New York, NY 10022	New York, NY 10009
both of United States of America	

[74] Address for Service:

PHILLIPS ORMONDE & FITZPATRICK  
367 Collins Street  
Melbourne 3000 Australia

Basic Convention Application Details:

[31] Application Number:	096096
[33] Country:	United States of America
Country Code:	US
[32] Date of Application	11 September 1987

Applicant states the following:

The nominated person has entitlement from the co-inventor by assignment.

The basic Convention application was the first made in a Convention country in respect of the invention for which priority is claimed under Part 2 of Chapter 8.

DATED: 28 January, 1992

PHILLIPS ORMONDE & FITZPATRICK

Attorneys for:

JOHN C. HARVEY

(57) Claim

1. A signal processor system comprising a carrier transmission receiving means;

means for demodulating said carrier transmission to detect an information transmission thereon,

detector means for identifying a signal embedded in said information transmission and removing it therefrom;

a first control means for instructing said detector to identify and pass a specified embedded detected signal;

a second control means for receiving said specified embedded detected signal from said first control means and for inputting said embedded signal into computer equipment external to said signal processor system;

and monitor means activated by said embedded signal to monitor the performance and/or output of said second control means.

9. A method of processing signals including:

(a) the step of receiving a carrier transmission;

(b) the step of demodulating said carrier transmission to detect an information transmission thereon;

(11) AU-B-25341/88  
(10) 624087

-2-

- (c) the step of identifying signals embedded in said information transmission and removing said signals therefrom;
- (d) the step of identifying and passing a specified signal embedded in said information transmission;
- (e) the step of receiving said specified signal and inputting said signal into external computer equipment; and
- (f) the step of monitoring the performance of step (e) in response to said embedded signals.

## AMENDED CLAIMS

[received by the International Bureau on 13 March 1989 (13.03.89);  
original claims 1-38 replaced by amended claims 1-38 (11 pages)]

1. In a signal processor system, carrier  
transmission receiving means; means for demodulating said  
carrier transmission to detect an information transmission  
thereon; detector means for detecting an embedded signal  
5 in the information transmission and removing it from said  
information transmission; first control means responsive  
to said detected signal to activate and/or deactivate  
equipment external to said signal processor system;  
second control means activated by said detected signal to  
10 monitor the performance and/or output of said first  
control means; a recorder means for receiving and  
recording data collected by said monitor means; and  
control means for instructing said recorder to direct  
information recorded thereon to a remote site.

15

2. In a signal processor, carrier transmission  
receiving means; means for demodulating said carrier  
transmission to detect an information transmission  
thereon; detector means for detecting an embedded signal  
20 in the information transmission and for removing said  
signal from said information transmission; control means  
responsive to said detected signal to activate and/or  
deactivate equipment external to said signal processor;  
monitor means activated by said detected signal to monitor  
25 the performance and/or output of said external equipment;  
a recorder means for receiving and recording data  
collected by said monitor means; control means for  
instructing said carrier receiving means to receive the  
appropriate carrier transmission within a predetermined  
30 time interval and to direct said received carrier  
transmission to said demodulating means and said detector  
means; and control means for instructing said recorder to  
direct information recorded thereon to a remote site.

3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.

4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said

carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said  
5 demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to  
10 said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.

15           5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information  
20 transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and  
25 recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means;  
30 control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.

35

6. The apparatus as claimed in claim 1 wherein the embedded signal is encrypted and including a decrypter means for decrypting said signal.

5           7. The apparatus as claimed in claim 2 wherein the embedded signal is encrypted and including a decrypter means for decrypting said signal.

10           8. The apparatus as claimed in claim 3 wherein the embedded signal is encrypted and including a decrypter means for decrypting said signal.

15           9. The apparatus as claimed in claim 4 wherein the embedded signal is encrypted and including a decrypter means for decrypting said signal.

20           10. A signal processor system comprising a carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for identifying a signal embedded in said information transmission and removing it therefrom; a first control means for instructing said detector to identify and pass a specified embedded detected signal; a second control means for receiving said  
25           specified embedded detected signal from said first control means and for inputting said embedded signal into computer equipment external to said signal processor system.

30           11. The apparatus as claimed in claim 2 including means for receiving and detecting embedded signals on a plurality of carrier transmissions.

35           12. The apparatus as claimed in claim 3 including means for receiving and detecting embedded signals on a plurality of carrier transmissions.

13. The apparatus as claimed in claim 4 including means for receiving and detecting embedded signals on a plurality of carrier transmissions.

5

14. The apparatus in claim 10 wherein the embedded signal is encrypted and including a decrypter means for decrypting said signal.

10

15. A method of processing signals including:

(a) the step of receiving a carrier transmission;  
(b) the step of demodulating said carrier transmission to detect an information transmission thereon;

15

(c) the step of detecting and identifying embedded signals on said information transmission;

(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;

20

(e) the step of controlling said devices based on the instructions within said embedded signals; and  
(f) the step of recording the receipt of and passing to said devices of said embedded signals.

25

16. A method of processing signals as claimed in claim 15 including the step of decrypting encrypted embedded signals.

30

17. A method of processing signals as claimed in claim 15 including the step of recording the response of the device or devices to be controlled by the embedded signals for later transmission to a remote site.

18. A method of processing signals as claimed in claim 15 including the step of decrypting an encrypted information transmission.

5           19. A method of processing signals as claimed in claim 15 including the step of removing a portion of said detected embedded signal.

10           20. A method of processing signals as claimed in claim 15 including the step of adding a second signal to the information transmission.

15           21. A method of generating computer output in a computer system that consists of a multiplicity of computers each of which is adapted to generate and transmit user specific output information content and a user specific signal to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:

20           transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and

            causing selected computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user application.

25           30           35

22. A method according to claim 21 wherein said  
last named output devices are system output devices and  
all information of said last named output signals is  
5 system output.

23. A method according to claim 21 including the  
additional steps of:

transmitting an instruct-to-select signal to  
10 said computers, containing user application data, and  
causing at least one selected computer to  
receive and record at least one selected application datum  
of its specific user application.

24. A method according to claim 22 including the  
additional steps of:

transmitting an instruct-to-select signal to  
said computers, containing user application data, and  
causing at least one selected computer to  
20 receive and record at least one selected application datum  
of its specific user application.

25. A method according to claim 23 wherein said  
last named computer is caused to receive and record said  
25 last named application datum prior to the transmission of  
said instruct-to-generate signal.

26. A method according to claim 23 wherein said  
instruct-to-select signal causes more than one computer to  
30 receive and record at least one selected application datum  
and selected data differ from computer to computer.

27. A method according to claim 25 wherein said  
instruct-to-select signal causes more than one computer to

receive and record at least one selected application datum and selected data differ from computer to computer.

28. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:

transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,

detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and

causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

29. A method according to claim 28 wherein said last named computers simultaneously start the generation of their user specific output information content.

30. A method according to claim 28 wherein at least one of said last named computers has capacity to commence or cease transmitting its output signals to its associated output device in response to said instruct-to-generate signal and said signal causes said computer to transmit said output signal.

31. A method according to claims 29 wherein at least one of said last named computers has capacity to commence or cease transmitting its output signals to its associated output device in response to said instruct-to-generate signal and said signal causes said computer to transmit said output signal.

32. A method according to claim 29 wherein said instruct-to-generate signal causes said computers to commence the generation of their user specific output information content then to transmit their output signals.

33. A method according to claim 32 wherein said last named computers commence transmitting their output signals simultaneously.

34. A method according to claim 28 wherein at least one of said last named computers has capacity to cease transmitting its user specific signal in response to the absence of said instruct-to-generate signal and the absence of said signal causes said one computer to cease transmitting their user specific signals.

35. A method according to one of claims 21-34 wherein said instruct-to-generate signal causes at least one of said computers to generate second user specific output information content before commencing to transmit a first user specific signal.

36. A method according to one of claims 21-34  
wherein said instruct-to-generate signal causes at least  
one of said computers to generate a second output signal  
5 comprising second user specific output information  
content and second user specific signal before  
transmission of a first output signal comprising first  
user specific output information content and a first user  
specific signal commences.

10

37. A method according to one of claims 21-34  
wherein said instruct-to-generate signal causes at least  
one of said computer to generate data that is transmitted  
to an output device that displays data to the human  
15 senses.

38. A method of generating computer output at a  
multiplicity of receiver stations each of which includes a  
computer adapted to generate and transmit user specific  
20 signals to one or more associated output devices, with at  
least some of said computers being programmed to process  
modification control signals so as to modify the user  
specific signals transmitted to their associated output  
devices, each of said computers being programmed to  
25 accommodate a special user application, comprising the  
steps of:

transmitting an instruct-to-process signal to  
said computers at a time when the corresponding output  
signals are not being transmitted to their associated  
30 output devices,

detecting the presence of said instruct-to-  
process signal at selected receiver stations and coupling  
said instruct-to-process signal to the computers  
associated with said selected stations,

causing said last named computers simultaneously to process computer information in accordance with their special user applications, thereby to commence generation of their user specific signals,

5 transmitting an instruct-to-output signal to said computers to cause each of said computers to output in accordance with its associated special user application, and

causing said last named computers to output  
10 their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to each of said output devices an output signal comprising the processed user specific output information content and the user specific signal of  
15 its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

SIGNAL PROCESSING APPARATUS AND METHODSCROSS-REFERENCE TO RELATED APPLICATIONS

5           This is a continuation-in-part of a patent application Ser. No. 829,531 filed February 14, 1986 which in turn was a continuation of a patent application Ser. No. 317,510 filed November 3, 1981.

BACKGROUND OF THE INVENTION

10           The invention relates to an integrated system of programming communication and involves the fields of computer processing, computer communications, television, radio, and other electronic communications; the fields of automating the  
15 handling, recording, and retransmitting of television, radio, computer, and other electronically transmitted programming; and the fields of regulating, metering, and monitoring the availability, use, and usage of such programming.

          For years, television has been recognized as a most  
20 powerful medium for communicating ideas. And television is so-called "user friendly"; that is, despite technical complexity, television is easy for subscribers to use.

          Radio and electronic print services such as stock brokers' so-called "tickers" and "broad tapes" are also  
25 powerful, user friendly mass media. (Hereinafter, the electronic print mass medium is called, "broadcast print.")

          But television, radio, and broadcast print are only mass media. Program content is the same for every viewer. Occasionally one viewer may see, hear, or read information of  
30 specific relevance to him (as happens when a guest on a television talk show turns to the camera and says, "Hi, Mom"), but such electronic media have no capacity for conveying user specific information simultaneously to each user.

          For years, computers have been recognized as having  
35 unsurpassed capacity for processing and displaying user

2

specific information.

But computer processing is not a mass medium. Computers operate under the control of computer programs that are inputted by specific users for specific purposes, not  
5 programs that are broadcast to and executed simultaneously at the stations of mass user audiences. And computer processing is far less user friendly than, for example, television.

Today great potential exists for combining the capacity of broadcast communications media to convey ideas  
10 with the capacity of computers to process and output user specific information. One such combination would provide a new radio-based or broadcast print medium with the capacity for conveying general information to large audiences--e.g., "Stock prices rose today in heavy trading,"--with information  
15 of specific relevance to each particular user in the audience--e.g., "but the value of your stock portfolio went down." (Hereinafter, the new media that result from such combinations are called "combined" media.)

Unlocking this potential is desirable because these  
20 new media will add substantial richness and variety to the communication of ideas, information and entertainment. Understanding complex subjects and making informed decisions will become easier.

To unlock this potential fully requires means and  
25 methods for combining and controlling receiver systems that are now separate--television and computers, radio and computers, broadcast print and computers, television and computers and broadcast print, etc.

But it requires much more.

To unlock this potential fully requires a system with  
30 efficient capacity for satisfying the demands of subscribers who have little receiver apparatus and simple information demands as well as subscribers who have extensive apparatus and complex demands. It requires capacity for transmitting  
35 and organizing vastly more information and programming than

3

any one-channel transmission system can possibly convey at one time. It requires capacity for controlling intermediate transmission stations that receive information and programming from many sources and for organizing the  
5 information and programming and retransmitting the information and programming so as to make the use of the information and programming at ultimate receiver stations as efficient as possible.

To unlock this potential also requires efficient  
10 capacity for providing reliable audit information to (1) advertisers and others who pay for the transmission and performance of programming and (2) copyright holders, pay service operators, and others such as talent who demand, instead, to be paid. This requires capacity for identifying  
15 and recording (1) what television, radio, data, and other programming and what instruction signals are transmitted at each transmission station and (2) what is received at each receiver station as well as (3) what received programming is combined or otherwise used at each receiver station and (4)  
20 how it is received, combined, and/or otherwise used.

Moreover, this system must have the capacity to ensure that programming supplied for pay or for other conditional use is used only in accordance with those conditions. For example, subscriber station apparatus must display the  
25 commercials that are transmitted in transmissions that advertisers pay for. The system must have capacity for decrypting, in many varying ways, programming and instruction signals that are encrypted and for identifying those who pirate programming and inhibiting piracy.

It is the object of this invention to unlock this  
30 great potential in the fullest measure by means of an integrated system of programming communication that joins together all these capacities most efficiently.

Computer systems generate user specific information,  
35 but in any given computer system, any given set of program

4

instructions that causes and controls the generation of user specific information is inputted to only one computer at a time.

Computer communications systems do transmit data point-to-multipoint. The Dataspeed Corporation division of Lotus Development Corporation of Cambridge, Massachusetts transmits real-time financial data over radio frequencies to microcomputers equipped with devices called "modios" that combine the features of radio receivers, modems, and decryptors. The Equatorial Communications Company of Mountain View, California transmits to similarly equipped receiver systems by satellite. At each receiver station, apparatus receive the particular transmission and convert its data content into unencrypted digital signals that computers can process. Each subscriber programs his subscriber station apparatus to select particular data of interest.

This prior art is limited. It only transmits data; it does not control data processing. No system is preprogrammed to simultaneously control a plurality of central processor units, operating systems, and pluralities of computer peripheral units. None has capacity to cause simultaneous generation of user specific information at a plurality of receiver stations. None has any capacity to cause subscriber station computers to process received data, let alone in ways that are not inputted by the subscribers. None has any capacity to explain automatically why any given information might be of particular interest to any subscriber or why any subscriber might wish to select information that is not selected or how any subscriber might wish to change the way selected information is processed.

As regards broadcast media, systems in the prior art have capacity for receiving and displaying multiple images on television receivers simultaneously. One such system for superimposing printed characters transmitted incrementally during the vertical blanking interval of the television

5

scanning format is described in U. S. Patent to Kimura No. 3,891,792. U.S. Patent to Baer No. 4,310,854 describes a second system for continuously displaying readable alphanumeric captions that are transmitted as digital data 5 superimposed on a normal FM sound signal and that relate in program content to the conventional television information upon which they are displayed. These systems permit a viewer to view a primary program and a secondary program.

This prior art, too, is limited. It has no capacity 10 to overlay any information other than information transmitted to all receiver stations simultaneously. It has no capacity to overlay any such information except in the order in which it is received. It has no capacity to cause receiver station computers to generate any information whatsoever, let alone 15 user specific information. It has no capacity to cause overlays to commence or cease appearing at receiver stations, let alone commence and cease appearing periodically.

As regards the automation of intermediate transmission stations, various so-called "cueing" systems in the prior art 20 operate in conjunction with network broadcast transmissions to automate the so-called "cut-in" at local television and radio stations of locally originated programming such as so-called "local spot" advertisements.

Also in the prior art, U.S. Patent to Lambert No. 25 4,381,522 describes a cable television system controlled by a minicomputer that responds to signals transmitted from viewers by telephone. In response to viewers' input preferences, the computer generates a schedule which determines what prerecorded, so-called local origination 30 programs will be transmitted, when, and over what channels. The computer generates a video image of this schedule which it transmits over one cable channel to viewers which permits them to see when they can view the programs they request and over what channels. Then, in accordance with the schedule, 35 it actuates preloaded video tape, disc or film players and

transmits the programming transmissions from these players to the designated cable channels by means of a controlled video switch.

This prior art, too, is limited. It has no capacity to  
5 schedule automatically or transmit any programming other than that loaded immediately at the play heads of the controlled video players. It has no capacity to load the video players or identify what programming is loaded on the players or verify that scheduled programs are played correctly. It has  
10 no capacity to cause the video players to record programming from any source. It has no capacity to receive programming transmissions or process received transmissions in any way. It has no capacity to operate under the control of instructions transmitted by broadcasters. It has no capacity  
15 to insert signals that convey information to or control, in any way, the automatic operation of ultimate receiver station apparatus other than television receivers.

As regards the automation of ultimate receiver stations, in the prior art, U.S. Patent to Bourassin et al.  
20 No. 4,337,480 describes a dynamic interconnection system for connecting at least one television receiver to a plurality of television peripheral units. By means of a single remote keyboard, a viewer can automatically connect and disconnect any of the peripheral units without the need manually to  
25 switch systems or fasten and unfasten cabling each time. In addition, using a so-called "image-within-image" capacity, the viewer can superimpose a secondary image from a second peripheral unit upon the primary image on the television display. In this fashion, two peripheral units can be viewed  
30 simultaneously on one television receiver. U.S. Patent to Freeman et. al. No. 4,264,925 describes a multi-channel programming transmission system wherein subscribers may select manually among related programming alternatives transmitted simultaneously on separate channels.

35 This prior art, too, is limited. It has no capacity

for interconnecting or operating a system at any time other than the time when the order to do so is entered manually at the system or remote keyboard. It has no capacity for acting on instructions transmitted by broadcasters to interconnect, 5 actuate or tune systems peripheral to a television receiver or to actuate a television receiver or automatically change channels received by a receiver. It has no capacity for coordinating the programming content transmitted by any given peripheral system with any other programming transmitted to a 10 television receiver. It has no capacity for controlling two separate systems such as, for example, an automatic radio and television stereo simulcast. It has no capacity for selectively connecting radio receivers to radio peripherals such as computers or printers or speakers or for connecting 15 computers to computer peripherals (except perhaps a television set). It has no capacity for controlling the operation of decryptors or selectively inputting transmissions to decryptors or outputting transmissions from decryptors to other apparatus. It has no capacity for 20 monitoring and maintaining records regarding what programming is selected or played on any apparatus or what apparatus is connected or how connected apparatus operate.

The prior art includes a variety of systems for monitoring programming and generating so-called "ratings." 25 One system that monitors by means of embedded digital signals is described in U.S. Patent to Haselwood, et al. No. 4,025,851. Another that monitors by means of audio codes that are only "substantially inaudible" is described in U.S. Patent to Crosby No. 3,845,391. A third that automatically 30 monitors a plurality of channels by switching sequentially among them and that includes capacity to monitor audio and visual quality is described in U.S. Patent to Greenberg No. 4,547,804.

This prior art, too, is limited. It has capacity to 35 monitor only single broadcast stations, channels or units and

lacks capacity to monitor more than one channel at a time or to monitor the combining of media. At any given monitor station, it has had capacity to monitor either what is transmitted over one or more channels or what is received on one or more receivers but not both. It has assumed monitored signals of particular format in particular transmission locations and has lacked capacity to vary formats or locations or to distinguish and act on the absence of signals or to interpret and process in any fashion signals that appear in monitored locations that are not monitored signals. It has lacked capacity to identify encrypted signals then decrypt them. It has lacked capacity to record and also transfer information to a remote geographic location simultaneously.

As regards recorder/player systems, many means and methods exist in the prior art for recording television or audio programming and/or data on magnetic, optical or other recording media and for retransmitting prerecorded programming. Video tape recorders have capacity for automatic delayed recording of television transmissions on the basis of instructions input manually by viewers. So-called "interactive video" systems have capacity for locating prerecorded television programming on a given disc and transmitting it to television receivers and locating prerecorded digital data on the same disc and transmitting them to computers.

This prior art, too, is limited. It has no capacity for automatically embedding signals in and/or removing embedded signals from a television transmission then recording the transmission. It has no capacity for controlling the connection or actuation or tuning of external apparatus. It has no capacity for retransmitting prerecorded programming and controlling the decryption of said programming, let alone doing so on the basis of signals that are embedded in said programming that contain keys for the

decryption of said programming. It has no capacity for operating on the basis of control signals transmitted to recorder/players at a plurality of subscriber stations, let alone operating on the basis of such signals to record user  
5 specific information at each subscriber station.

As regards decoders and decryptors, many different systems exist, at present, that enable programming suppliers to restrict the use of transmitted programming to only duly authorized subscribers. The prior art includes so-called  
10 "addressable" systems that have capacity for controlling specific individual subscriber station apparatus by means of control instructions transmitted in broadcasts. Such systems enable broadcasters to turn off subscriber station decoder/decryptor apparatus of subscribers who do not pay  
15 their bills and turn them back on when the bills are paid.

This prior art, too, is limited. It has no capacity for decrypting combined media programming. It has no capacity for identifying then selectively decrypting control instructions embedded in unencrypted programming  
20 transmissions. It has no capacity for identifying programming transmissions or control instructions selectively and transferring them to a decryptor for decryption. It has no capacity for transferring the output of a decryptor selectively to one of a plurality of output apparatus. It  
25 has no capacity for automatically identifying decryption keys and inputting them to a decryptor to serve as the key for any step of decryption. It has no capacity for identifying and recording the identity of what is input to or output from a decryptor. It has no capacity for decrypting a transmission  
30 then embedding a signal in the transmission--let alone for simultaneously embedding user specific signals at a plurality of subscriber stations. It has no capacity for distinguishing the absence of an expected signal or controlling any operation when such absence occurs.

35 Further significant limitations arise out of the

/0

failure to reconcile aspects of these individual areas of art--monitoring programming, automating ultimate receiver stations, decrypting programming, generating the programming itself, etc.--into an integrated system. These limitations  
5 are both technical and commercial.

For example, the commercial objective of the aforementioned monitoring systems of Crosby, Haselwood et. al., and Greenberg is to provide independent audits to advertisers and others who pay for programming transmissions.  
10 All require embedding signals in programming that are used only to identify programming. Greenberg, for example, requires that a digital signal be transmitted at a particular place on a select line of each frame of a television program. But television has only so much capacity for transmitting  
15 signals outside the visible image; it is inefficient for such signals to serve only one function; and broadcasters can foresee alternate potential for this capacity that may be more profitable to them. Furthermore, advertisers recognize that if the systems of Crosby, Haselwood and Greenberg  
20 distinguish TV advertisements by means of single purpose signals, television receivers and video tape recorders can include capacity for identifying said signals and suppressing the associated advertisements. Accordingly, no independent automatic comprehensive so-called "proof-of-performance"  
25 audit service has yet proven commercially viable.

As a second example, because of the lack of a viable independent audit system, each service that broadcasts encrypted programming controls and services at each subscriber station one or more receiver/decryptors dedicated  
30 to its service alone. Lacking a viable audit system, services do not transmit to shared, common receiver/decryptors.

These are just two examples of limitations that arise in the absence of an integrated system of programming  
35 communication.

//

It is an object of the present invention to overcome these and other limitations of the prior art.

#### SUMMARY OF THE INVENTION

5       The present invention consists of an integrated system of methods and apparatus for communicating programming. The term "programming" refers to everything that is transmitted electronically to entertain, instruct or inform, including television, radio, broadcast print, and computer programming  
10 as well as combined medium programming. The system includes capacity for automatically organizing multi-channel communications. Like television, radio, broadcast print, and other electronic media, the present invention has capacity for transmitting to standardized programming that is very  
15 simple for subscribers to play and understand. Like computer systems, the present invention has capacity for transmitting data and control instructions in the same information stream to many different apparatus at a given subscriber station, for causing computers to generate and transmit programming,  
20 and for causing receiver apparatus to operate on the basis of programming and information received at widely separated times.

It is the further purpose of this invention to provide means and methods whereby a simplex point-to-multipoint  
25 transmission (such as a television or radio broadcast) can cause simultaneous generation of user specific information at a plurality of subscriber stations. One advantage of the present invention is great ease of use. For example, as will be seen, a subscriber can cause his own information to be  
30 processed in highly complex ways by merely turning his television receiver on and tuning to a particular channel. Another advantage of the present invention is its so-called "transparency"--subscribers see none of the complex processing taking place. Another advantage is privacy. No  
35 private information is required at transmitting stations, and

12

no subscriber's information is available at any other subscriber's station.

It is the further purpose of this invention to provide means and methods whereby a simplex broadcast transmission  
5 can cause periodic combining of relevant user specific information and conventional broadcast programming simultaneously at a plurality of subscriber stations, thereby integrating the broadcast information with each user's own information. One advantage of the present invention is its  
10 use of powerful communication media such as television to reveal the meaning of the results of complex processing in ways that appear clear and simple. Another advantage is that receiver stations that lack said capacity for combining user specific information into television or radio programming can  
15 continue, without modification, to receive and display the conventional television or radio and without the appearance of any signals or change in the conventional programming.

It is the further purpose of this invention to provide means and methods for the automation of intermediate  
20 transmission stations that receive and retransmit programming. The programming may be delivered by any means including over-the-air, hard-wire, and manual means. The stations may transmit programming over-the-air (hereinafter, "broadcast") or over hard-wire (hereinafter, "cablecast").  
25 They may transmit single channels or multiple channels. The present invention includes capacity for automatically constructing records for each transmitted channel that duplicate the logs that the Federal Communications Commission requires broadcast station operators to maintain.

It is the further purpose of this invention to provide  
30 means and methods for the automation of ultimate receiver stations, especially the automation of combined medium and multi-channel presentations. Such ultimate receiver stations may be private homes or offices or commercial establishments  
35 such as theaters, hotels, or brokerage offices.

/3

It is the further purpose of this invention to provide means and methods for identifying and recording what television, radio, data, and other programming is transmitted at each transmission station, what programming is received at 5 each receiver station, and how programming is used. In the present invention, certain monitored signals may be encrypted, and certain data collected from such monitoring may be automatically transferred from subscriber stations to one or more remote geographic stations.

10 It is a further purpose of this invention to provide means and methods for recording combined media and/or multi-channel programming and for playing back prerecorded programming of such types.

It is a further purpose of this invention to provide a 15 variety of means and methods for restricting the use of transmitted communications to only duly authorized subscribers. Such means and methods include techniques for encrypting programming and/or instructions and decrypting them at subscriber stations. They also include techniques 20 whereby the pattern of the composition, timing, and location of embedded signals may vary in such fashions that only receiving apparatus that are preinformed regarding the patterns that obtain at any given time will be able to process the signals correctly.

25 The present invention employs signals embedded in programming. Embedded signals provide several advantages. They cannot become separated inadvertently from the programming and, thereby, inhibit automatic processing. They occur at precise times in programming and can synchronize the 30 operation of receiver station apparatus to the timing of programming transmissions. They can be conveniently monitored.

In the present invention, the embedded signals contain digital information that may include addresses of specific 35 receiver apparatus controlled by the signals and instructions

14

that identify particular functions the signals cause addressed apparatus to perform.

In programming transmissions, given signals may run and repeat, for periods of time, continuously or at regular intervals. Or they may run only occasionally or only once. They may appear in various and varying locations. In television they may appear on one line in the video portion of the transmission such as line 20 of the vertical interval, or on a portion of one line, or on more than one line, and they will probably lie outside the range of the television picture displayed on a normally tuned television set. In television and radio they may appear in a portion of the audio range that is not normally rendered in a form audible to the human ear. In television audio, they are likely to lie between eight and fifteen kilohertz. In broadcast print and data communications transmissions, the signals may accompany conventional print or data programming in the conventional transmission stream but will include instructions that receiver station apparatus are preprogrammed to process that instruct receiver apparatus to separate the signals from the conventional programming and process them differently. In all cases, signals may convey information in discrete words, transmitted at separate times or in separate locations, that receiver apparatus must assemble in order to receive one complete instruction.

(The term "signal unit" hereinafter means one complete signal instruction or information message unit. Examples of signal units are a unique code identifying a programming unit, or a unique purchase order number identifying the proper use of a programming unit, or a general instruction identifying whether a programming unit is to be retransmitted immediately or recorded for delayed transmission. The term "signal word" hereinafter means one full discrete appearance of a signal as embedded at one time in one location on a transmission. Examples of signal words are a string of one

15

or more digital data bits encoded together on a single line of video or sequentially in audio. Such strings may or may not have predetermined data bits to identify the beginnings and ends of words. Signal words may contain parts of signal  
5 units, whole signal units, or groups of partial or whole signal units or combinations.)

In the present invention, particular signal processing apparatus (hereinafter called the "signal processor") detect signals and, in accordance with instructions in the signals  
10 and preprogramming in the signal processor, decrypt and/or record and/or control station apparatus by means of the signals and/or discard the signals. The apparatus include one or more devices that can selectively scan transmission frequencies as directed and, separately, capacity to receive  
15 signals from one or more devices that continuously monitor selected frequencies. The frequencies may convey television, radio, or other programming transmissions. The input transmissions may be received by means of antennas or from hard-wire connections. The scanners/switches, working in  
20 parallel or series or combinations, transfer the transmissions to receiver/decoder/detectors that identify signals encoded in programming transmissions and convert the encoded signals to digital information; decryptors that may convert the received information, in part or in whole, to  
25 other digital information according to preset methods or patterns; and one or more processor/monitors and/or buffer/comparators that organize and transfer the information stream. The processors and buffers can have inputs from each of the receiver/detector lines and evaluate information  
30 continuously. From the processors and buffers, the signals may be transferred to external equipment such as computers, videotape recorders and players, etc. And/or they may be transferred to one or more internal digital recorders that receive and store in memory the recorded information and have  
35 connections to one or more remote sites for further

16

transmission of the recorded information. The apparatus has means for external communication and an automatic dialer and can contact remote sites and transfer stored information as required in a predetermined fashion or fashions. The  
5 apparatus has a clock for determining and recording time as required. It has a read only memory for recording permanent operating instructions and other information and a programmable random access memory controller ("PRAM controller") that permits revision of operating patterns and  
10 instructions. The PRAM controller may be connected to all internal operating units for full flexibility of operations.

Signal processing apparatus that are employed in specific situations that require fewer functions than those provided by the signal processor described above may omit one  
15 or more of the specific operating elements described above.

A central objective of the present invention is to provide flexibility in regard to installed station apparatus. At any given time, the system must have capacity for wide variation in individual station apparatus in order to provide  
20 individual subscribers the widest range of information options at the least cost in terms of installed equipment. Flexibility must exist for expanding the capacity of installed systems by means of transmitted software and for altering installed systems in a modular fashion by adding or  
25 removing components. Flexibility must exist for varying techniques that restrict programming to duly authorized subscribers in order to identify and deter pirates of programming.

Other objects, features, and advantages of this  
30 invention will appear in the following descriptions and the appended claims.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a block diagram of a video/computer combined  
35 medium receiver station.

17

Fig. 1A shows a representative example of a computer generated, user specific graphic as it would appear by itself on the face of a display tube.

Fig. 1B shows a representative example of a studio generated graphic displayed on the face of a display tube.

Fig. 1C shows a representative example, on the face of a display tube, of a studio graphic combined with a user specific graphic .

Fig. 2 is a block diagram of one embodiment of a signal processor.

Fig. 2A is a block diagram of a TV signal decoder apparatus.

Fig. 2B is a block diagram of a radio signal decoder apparatus.

Fig. 2C is a block diagram of an other signal decoder apparatus.

Fig. 2D is a block diagram of one embodiment of a receiver station signal processing system.

Fig. 2E illustrates one example of the composition of signal information and shows the initial binary information of a message that contains execution, meter-monitor, and information segments.

Fig. 2F shows one instance of a meter-monitor segment.

Fig. 2G shows one instance of a command that fills a whole number of byte signal words incompletely.

Fig. 2H shows one instance of a message that contains execution and meter-monitor segments and consists of the command of Fig. 2G with three padding bits added at the end to complete the last byte signal word.

Fig. 2I shows one instance of a SPAM message stream.

Fig. 2J shows one instance of a message that consists of just a header and an execution segment and fills one byte signal word completely.

Fig. 2H shows one instance of a message that contains execution and meter-monitor segments and fills a whole number

18

of byte signal words completely but ends with one full byte signal word of padding bits because the last byte signal word of command information is an EOFs word.

Fig. 3 is a block diagram of a video/computer combined medium receiver station with a signal processing system.

Fig. 3A is a block diagram of the preferred embodiment the controller apparatus of a SPAM decoder.

Fig. 4 is a block diagram of one example of a signal processing programming reception and use regulating system.

Fig. 5 is a block diagram of one example of a signal processing apparatus and methods monitoring system installed to monitor a subscriber station.

Fig. 6 is a block diagram of one example of signal processing apparatus and methods at an intermediate transmission station, in this case a cable system headend.

Fig. 7 is a block diagram of signal processing apparatus and methods at an ultimate receiver station.

Fig. 7A is a block diagram of signal processing apparatus and methods with external equipment regulating the environment of the local receiver site.

Fig. 7B is a block diagram of signal processing apparatus and methods used to control a combined medium, multi-channel presentation and to monitor such viewership.

Fig. 7C is a block diagram of signal processing apparatus and methods selecting receivable information and programming and controlling combined medium, multi-channel presentations.

Fig. 7D is a block diagram of a radio/computer combined medium receiver station.

Fig. 7E is a block diagram of a television/computer combined medium receiver station.

Fig. 7F is a block diagram of an example of controlling television and print combined media.

Fig. 8 is a block diagram of selected apparatus of the station of Fig. 7 with a station specific EPROM, 20B,

installed.

### DESCRIPTION OF THE PREFERRED EMBODIMENTS

#### 5 ONE COMBINED MEDIUM

Fig. 1 shows a video/computer combined medium subscriber station. Via conventional antenna, the station receives a conventional television broadcast transmission at television tuner, 215. The Model CV510 Electronic TV Tuner of the Zenith Radio Corporation of Chicago, Illinois, which is a component of the Zenith Video Hi-Tech Component TV system, is one such tuner. This tuner outputs conventional audio and composite video transmissions. The audio transmission is inputted to TV monitor, 202M. The video transmission is inputted to video transmission divider, 4, which is a conventional divider that splits the transmission into two paths. One is inputted continuously to TV signal decoder, 203, and the other to microcomputer, 205. TV signal decoder, 203, which is described more fully below, has capacity for receiving a composite video transmission; detecting digital information embedded therein; correcting errors in the received information by means of forward error checking techniques, well known in the art; converting the received information, as may be required, by means of input protocol techniques, well known in the art, into digital signals that microcomputer, 205, can receive and process and that can control the operation of microcomputer, 205; and transferring said signals to microcomputer, 205. Microcomputer, 205, is a conventional microcomputer system with disk drives that is adapted to have capacity for receiving signals from decoder, 203; for generating computer graphic information; for receiving a composite video transmission; for combining said graphic information onto the video information of said transmission by graphic overlay techniques, well known in the art; and for outputting the

20

resulting combined information to a TV monitor, 202M, in a composite video transmission. One such system is the IBM Personal Computer of International Business Machines Corporation of Armonk, New York with an IBM Asynchronous Communications Adapter installed in one expansion slot and a PC-MicroKey Model 1300 System with Techmar Graphics Master Card, as supplied together by Video Associates Labs of Austin, Texas, installed in two other slots. Microcomputer, 205, receives digital signals from decoder, 203, at its asynchronous communications adapter and the video transmission from divider, 4, at its PC-MicroKey 1300 System. It outputs the composite video transmission at its PC-MicroKey System. Microcomputer, 205, has all required operating system capacity--eg., the MS/DOS Version 2.0 Disk Operating System of Microsoft, Inc. of Bellvue, Washington with installed device drivers. TV monitor, 202M, has capacity for receiving composite video and audio transmissions and for presenting a conventional television video image and audio sound. One such monitor is the Model CV1950 Color Monitor of the Zenith Radio Corporation.

In the example, the subscriber station of Fig. 1 is in New York City and is tuned to the conventional broadcast television transmission frequency of channel 13 at 8:30 PM on a Friday evening when the broadcast station of said frequency, WNET, commences transmitting a television program about stock market investing, "Wall Street Week." Said WNET station is an intermediate transmission station for said program which actually originates at a remote television studio in Owings Mills, Maryland. (Hereinafter, a studio or station that originates the broadcast transmission of programming is called the "program originating studio.") From said program originating studio said program is transmitted by conventional television network feed transmission means, well known in the art, to a large number of geographically dispersed intermediate transmission stations that retransmit

21

said program to millions of subscriber stations where subscribers view said program. Said network transmission means may include so-called landlines, microwave transmissions, a satellite transponder, or other means.

5           At said subscriber station, microprocessor, 205, contains a conventional 5 1/4" floppy disk at a designated one of its disk drives that holds a data file recorded in a fashion well known in the art. Said file contains information on the portfolio of financial instruments owned  
10 by the subscriber that identifies the particular stocks in the portfolio, the number of shares of each stock owned at the close of business of each business day from the end of the previous week, and the closing share prices applicable each day. Decoder, 203, is preprogrammed to detect digital  
15 information on a particular line or lines (such as line 20) of the vertical interval of its video transmission input; to correct errors in said information; to convert said corrected information into digital signals usable by microcomputer, 205; and to input said signals to microcomputer, 205, at its  
20 asynchronous communications adapter. Microcomputer, 205, is preprogrammed to receive said input of signals at its asynchronous communications adapter and to respond in a predetermined fashion to instruction signals embedded in the "Wall Street Week" programming transmission.

25           Other similarly configured and preprogrammed subscriber stations also tune to the transmission of said "Wall Street Week" program by given intermediate transmission stations. At each subscriber station, the records in the contained financial portfolio file hold, in identical format,  
30 information on the particular investments of that station's subscriber.

At the start of the transmission of said "Wall Street Week" program, all subscriber station apparatus is on and fully operational.

35           At said program originating studio, at the outset of

22

said program transmission, a first series of control instructions is generated, embedded sequentially on said line or lines of the vertical interval; and transmitted on the first and each successive frame of said television program transmission, signal unit by signal unit and word by word, until said series has been transmitted in full. The instructions of said series are addressed to and control the microcomputer, 205, of each subscriber station.

In said series in full--and in any one or more subsequent series of instructions--particular instructions are separated, as may be required, by time periods when no instruction that controls the microcomputer, 205, of any station is transmitted which periods allow sufficient time for the microcomputer, 205, of each and every subscriber station to complete functions controlled by previously transmitted instructions and commence waiting for a subsequent instruction, in a waiting fashion well known in the art, before receiving a subsequent instruction.

Tuner, 215, receives this television transmission, converts the received television information into audio and composite video transmissions, and transmits the audio to monitor, 202M, and the video via divider, 4, to microcomputer, 205, and decoder, 203. Decoder, 203, detects the embedded instruction information, corrects it as required, converts it into digital signals usable by microcomputer, 205, and transmits said signals to microcomputer, 205.

With each step occurring in a predetermined fashion or fashions, well known in the art, this first set of instructions commands microcomputer, 205, (and all other subscriber station microcomputers simultaneously) to interrupt the operation of its central processor unit (hereinafter, "CPU") and any designated other processors; then to record the contents of the registers of its CPU and any other designated processors either at a designated place

23

in random access memory (hereinafter, "RAM") or on the contained disk; then to set its PC-MicroKey 1300 to the "GRAPHICS OFF" operating mode in which mode it transmits all received composite video information to monitor, 202M,  
5 without modification; then to record all information in RAM with all register information in an appropriately named file such as "INTERUPT.BAK" at a designated place on the contained disk; then to clear all RAM (except for that portion of RAM containing the so-called "operating system" of said  
10 microcomputer, 205) and all registers of said CPU and any other designated processors; then to wait for further instructions from decoder, 203.

Operating in said preprogrammed fashion under control of said first set of instructions, microcomputer, 205,  
15 reaches a stage at which the subscriber can input information only under control of signals embedded in the broadcast transmission and can reassume control of microcomputer, 205, (so long as microcomputer, 205, remains on and continues, in a predetermined fashion, to receive said embedded transmitted  
20 signals) only by executing a system reset (or so-called "warm boot") which on an IBM PC is accomplished by depressing simultaneously the "Ctrl", "Alt" and "Del" keys on the console keyboard.

(Hereinafter, this first set of instructions is called  
25 the "control invoking instructions," and the associated steps are called "invoking broadcast control.")

After completing all steps of invoking broadcast control, the microcomputer at each subscriber station (including microcomputer, 205) is preprogrammed (1) to  
30 evaluate particular initial instructions in each distinct series of received input instructions to ascertain how to process the information of said series and (2) to operate in a predetermined fashion or fashions in response to said initial instructions.

35 Subsequently, a second series of instructions is

24

embedded and transmitted at said program originating studio. Said second series is detected and converted into usable digital signals by decoder, 203, and inputted to microcomputer, 205, in the same fashion as the first series.

5 Microcomputer, 205, evaluates the initial signal word or words which instruct it to load at RAM (from the input buffer to which decoder, 203, inputs) and run the information of a particular set of instructions that follows said word or words just as the information of a file named FILE.EXE, recorded on the contained floppy disk, would be loaded at RAM (from the input buffer to which the disk drive of said disk inputs) and run were the command "FILE" entered from the console keyboard to the system level of the installed disk operating system. (Hereinafter, such a set of instructions that is loaded and run is called a "program instruction set.") In a fashion well known in the art, microcomputer, 205, loads the received binary information of said set at a designated place in RAM until, in a predetermined fashion, it detects the end of said set, and it executes said set as an assembled, machine language program in a fashion well known in the art.

Under control of said program instruction set and accessing the subscriber's contained portfolio data file for information in a fashion well known in the art,

25 microcomputer, 205, calculates the performance of the subscriber's stock portfolio and constructs a graphic image of that performance at the installed graphics card. The instructions cause the computer, first, to determine the aggregate value of the portfolio at each day's close of business by accumulating, for each day, the sum of the products of the number of shares of each stock held times that stock's closing price. The instructions then cause microcomputer, 205, to calculate the percentage change in the portfolio's aggregate value for each business day of the week in respect to the final business day of the prior week. Then

35

25

in a fashion well known in the art, the instructions cause microcomputer, 205, to enter digital bit information at the video RAM of the graphics card in a particular pattern that depicts the said percentage change as it would be graphed on  
5 a particular graph with a particular origin and set of scaled graph axes. Upon completion of these steps, the instructions cause microcomputer, 205, to commence waiting for a subsequent instruction from decoder, 203.

If the information at video RAM at the end of these  
10 steps were to be transmitted alone to the video screen of a TV monitor, it would appear as a line of a designated color, such as red, on a background color that is transparent when overlaid on a separate video image. Black is such a background color, and Fig. 1A shows one such line.

15 As each subscriber station completes the steps of calculation and graphic imaging performed under control of said program instruction set, information of such a line exists at video RAM at said station which information reflects the specific portfolio performance of the user of  
20 said station. Said information results from much computation, but the meaning of said information is hardly clear. Fig. 1A shows just a line.

While microcomputer, 205, performs these steps, TV monitor, 202M, displays the conventional television image and  
25 the sound of the transmitted "Wall Street Week" program. During this time the program may show the so-called "talking head" of the host as he describes the behavior of the stock market over the course of the week. Then the host says, "Now as we turn to the graphs, here is what the Dow Jones  
30 Industrials did in the week just past," and a studio generated graphic is transmitted. Fig. 1B shows the image of said graphic as it appears on the video screen of TV monitor, 202M. Then the host says, "And here is what your portfolio did." At this point, an instruction signal is generated at  
35 said program originating studio, embedded in the programming

26

transmission, and transmitted. Said signal is identified by decoder, 203; transferred to microcomputer, 205; and executed by microcomputer, 205, at the system level as the statement, "GRAPHICS ON". Said signal instructs microcomputer, 205, at 5 the PC-MicroKey 1300 to overlay the graphic information in its graphics card onto the received composite video information and transmit the combined information to TV monitor, 202M. TV monitor, 202M, then displays the image shown in Fig. 1C which is the microcomputer generated graphic 10 of the subscriber's own portfolio performance overlaid on the studio generated graphic. And microcomputer, 205, commences waiting for another instruction from decoder, 203.

By itself, the meaning of Fig. 1A is hardly clear. But when Fig. 1A is combined and displayed at the proper 15 time with the conventional television information, its meaning becomes readily apparent. Simultaneously, each subscriber in a large audience of subscribers sees his own specific performance information as it relates to the performance information of the market as a whole.

20 (Hereinafter, an instruction such as the above signal of "GRAPHICS ON" that causes subscriber station apparatus to execute a combining operation in synchronization is called a "combining synch command." Said initial signal word or words that preceded the above program instruction set provide 25 another example of a combining synch command in that said word or words synchronized all subscriber station computers in commencing loading and running information for a particular combining.)

While the TV monitor at this particular subscriber 30 station displays this particular subscriber's own overlay information, each other subscriber station displays the specific overlay information applicable at that station.

As the program proceeds, in the same fashion a further instruction signal is generated at said studio; transmitted; 35 detected; inputted from decoder, 203, to microcomputer, 205;

27

and executed as "GRAPHICS OFF." Then said studio ceases transmitting the graphic image, and transmits another image such as the host's talking head. Simultaneously, the GRAPHICS OFF command causes microcomputer, 205, to cease  
5 overlaying the graphic information onto the received composite video and to commence transmitting the received composite video transmission unmodified. Thereafter the "Wall Street Week" program proceeds, and microcomputer, 205, continues to operate under control of received instructions.

10 This combined medium example is of a television based medium. Like conventional television, said combined medium transmits the same signals to all subscriber stations. But unlike conventional television where each subscriber views only programming viewed by every other subscriber and where  
15 said programming is known to and available at the program originating studio, each subscriber of said combined medium views programming that is personalized and private. The programming he views is his own--in the example, his own portfolio performance--and his programming is not viewed by  
20 any other subscriber nor is it available at the program originating studio. In addition, personalized programming is displayed only when it is of specific relevance to the conventional television programming of said combined medium. In the example, each subscriber views a graphic presentation  
25 of his own portfolio performance information as soon as it becomes specifically relevant to graphic information of the performance of the market as a whole. Prior to its time of specific relevance, no personalized information is displayed (despite the fact that said graphic information of the performance of the market as a whole is displayed). And said  
30 personalized information is displayed only for so long as it remains specifically relevant. As soon as its specific relevance terminates, its display terminates.

This "Wall Street Week" portfolio performance example  
35 provides but one of many examples of television based

28

combined medium programming.

This television based combined medium is but one example of many combined media.

## 5 THE SIGNAL PROCESSOR

In the present invention, the signal processor--26 in Fig. 2; 26 in the signal processor system of Fig. 2D; in the signal processor system, 71, of Fig. 6; 200 in Fig. 7; and elsewhere--is focal means for the controlling and monitoring  
10 subscriber station operations. It meters communications and enables owners of information to offer their information to subscribers in many fashions on condition of payment. It has capacity for regulating communications consumption by selectively decrypting or not decrypting encrypted  
15 programming and/or control signals and capacity for assembling and retaining meter records at each subscriber station that document the consumption of specific programming and information at said station. It has capacity for identifying the subject matter of each specific unit of  
20 programming available on each of many transmission channels at each subscriber station as said unit becomes available for use and/or viewing which enables subscriber station apparatus to determine automatically whether the subject matter of said unit is of interest and, if so, to tune automatically to said programming. It has capacity, at each station, for receiving  
25 monitor information that identifies what programming is available, what programming is used, and how said programming is used and capacity for assembling and retaining monitor records that document said availability and usage. It has  
30 capacity for transferring said meter records automatically to one or more remote automated billing stations that account for programming and information consumption and bill subscribers and said monitor records automatically to one or more remote so-called "ratings" stations that collect  
35 statistical data on programming availability and usage. It

29

has capacities for processing information in many other fashions that will become apparent in this full specification.

Fig. 2 shows one embodiment of a signal processor.

5 Said processor, 26, is configured for simultaneous use with a cablecast input that conveys both television and radio programming and a broadcast television input.

At switch, 1, and mixers, 2 and 3, signal processor, 26, monitors all frequencies or channels available for  
10 reception at the subscriber station of Fig. 2 to identify available programming. The inputted information is the entire range of frequencies or channels transmitted on the cable and the entire range of broadcast television transmissions available to a local television antenna of  
15 conventional design. The cable transmission is inputted simultaneously to switch, 1, and mixer, 2. The broadcast transmission is inputted to switch, 1. Switch, 1, and mixers, 2 and 3, are all controlled by local oscillator and switch control, 6. The oscillator, 6, is controlled to  
20 provide a number of discrete specified frequencies for the particular radio and television channels required. The switch, 1, acts to select the broadcast input or the cablecast input and passes transmissions to mixer, 3, which, with the controlled oscillator, 6, acts to select a  
25 television frequency of interest that is passed at a fixed frequency to a TV signal decoder, 30. Simultaneously, mixer, 2, and the controlled oscillator, 6, act to select a radio frequency of interest which is inputted to a radio signal decoder, 40.

30 At decoders, 30 and 40, signal processor, 26, identifies specific programming and its subject matter as said programming becomes available for use and/or viewing. Decoder, 30, which is shown in detail in Fig. 2A, and decoder, 40, which is shown in Fig. 2B, detect signal  
35 information embedded in the respective inputted television

30

and radio frequencies, render said information into digital signals that subscriber station apparatus can process, modify particular ones of said signals through the addition and/or deletion of particular information, and output said signals 5 and said modified signals to buffer/comparator, 8. Said decoders are considered more fully below.

Buffer/comparator, 8, receives said signals from said decoders and other signals from other inputs and organizes the received information in a predetermined fashion.

10 Buffer/comparator, 8, has capacity for comparing a particular portions or portions of inputted information to particular preprogrammed information and for operating in preprogrammed fashions on the basis of the results of said comparing. It has capacity for detecting particular end of file signals in 15 inputted information and for operating in preprogrammed fashions whenever said information is detected.

The process of communication metering commences at buffer/comparator, 8. In a predetermined fashion, buffer/comparator, 8, determines whether a given instance of 20 received signal information requires decryption, either in whole or in part. In a fashion described more fully below, buffer/comparator, 8, and a controller, 20, which, too, is described more fully below, determine whether signal processor, 26, is enabled to decrypt said information. If 25 signal processor, 26, is so enabled, buffer/comparator, 8, transfers said information to decryptor, 10. If signal processor, 26, is not so enabled, buffer/comparator, 8, discards said information in a predetermined fashion. Buffer/comparator, 8, transfers signals that do not require 30 decryption directly to processor or controller, 12.

Decryptor, 10, is a standard digital information decryptor, well known in the art, that receives signals from buffer/comparator, 8, and under control of said controller, 20, uses conventional decryptor techniques, well known in the 35 art, to decrypt said signals as required. Decryptor, 10,

31

transfers decrypted signals to controller, 12.

Controller, 12, is a standard controller, well known in the art, that has microprocessor and RAM capacities and one or more ports for transmitting information to external apparatus. Said microprocessor capacity of controller, 12, is of a conventional type, well known in the art, but is specifically designed to have particular register memories, discussed more fully below. Controller, 12, may contain read only memory (hereinafter, "ROM").

Controller, 12, receives the signals inputted from buffer/comparator, 8, and decryptor, 10; analyzes said signals in a predetermined fashion; and determines whether they are to be transferred to external equipment or to buffer/comparator, 14, or both. If a signal or signals are to be transferred externally, in a predetermined fashion controller, 12, identifies the external apparatus to which the signal or signals are addressed and transfers them to the appropriate port or ports for external transmission. If they contain meter and/or monitor information and are to be processed further, controller, 12, selects, assembles, and transfers the appropriate information to buffer/comparator, 14. Controller, 12, has capacity to modify received signals by adding and/or deleting information and can transfer a given signal to one apparatus with one modification and to another apparatus with another modification (or with no modification). Controller, 12, receives time information from clock, 18, and has means to delay in a predetermined fashion the transfer of signals when, in a predetermined fashion, delayed transfer is determined to be required.

Buffer/comparator, 14, receives signal information that is meter information and/or monitor information from controller, 12, and from other inputs; organizes said received information into meter records and/or monitor records (called, in aggregate, hereinafter, "signal records") in a predetermined fashion or fashions; and transmits said

(32)

signal records to a digital recorder, 16, and/or to one or more remote sites. With respect to particular simple or frequently repeated instances of signal information, buffer/comparator, 8, has capacity to determine, in a  
5 predetermined fashion or fashions, what received information should be recorded, how it should be recorded, and when it should be transmitted to recorder, 16, and/or to said remote sites and to initiate or modify signal records and to discard unnecessary information accordingly. To avoid overloading  
10 digital recorder, 16, with duplicate data, buffer/comparator, 14, has means for counting and/or discarding duplicate instances of particular signal information and for incorporating count information into signal records. Buffer/comparator, 14, receives time information from clock,  
15 18, and has means for incorporating time information into signal records. Buffer/comparator, 14, also has means for transferring received information immediately to a remote site or sites via telephone connection, 22, and for communicating a requirement for such transfer to controller,  
20 20, which causes such transfer. Buffer/comparator, 14, operates under control of controller, 20, and has capacity whereby controller, 20, can cause modification of the formats of and information in signal records at buffer/comparator, 14. (In circumstances where information collecting and  
25 processing functions are extensive--for example, when a given buffer/comparator, 14, must collect monitor information at a subscriber station with apparatus and/or communications flows that are extensive and complex--buffer/comparator, 14, may operate under control of a dedicated, so-called "on-board"  
30 controller, 14A, at buffer/comparator, 14, which is preprogrammed with appropriate control instructions and is controlled by controller, 20, similarly to the fashion in which controller, 12 is controlled by controller, 20.)

Digital recorder, 16, is a memory storage element of  
35 standard design that receives information from

33

buffer/comparator, 14, and records said information in a predetermined fashion. In a predetermined fashion, recorder, 16, can determine how full it is and transmit this information to controller, 20. Recorder, 16, may inform  
5 controller, 20, automatically when it reaches a certain level of fullness.

Signal processor, 26, has a controller device which includes programmable RAM controller, 20; ROM, 21, that may contain unique digital code information capable of  
10 identifying signal processor, 26, and the subscriber station of said processor, 26, uniquely; an automatic dialing device 24; and a telephone unit, 22. A particular portion of ROM, 21, is erasable programmable ROM (hereinafter, "EPROM") or other forms of programmable nonvolatile memory. Under  
15 control particular preprogrammed instructions at that portion of ROM, 21, that is not erasable, signal processor, 26, has capacity to erase and reprogram said EPROM in a fashion that is described more fully below. Controller, 20, has capacity for controlling the operation of all elements of the signal  
20 processor and can receive operating information from said elements. Controller, 20, has capacity to turn off any element or elements of controlled subscriber station apparatus, in whole or in part, and erase any or all parts of erasable memory of said controlled apparatus.

25 As an apparatus in the unified system of programming communication of the present invention, a signal processor can monitor any combination of inputs and transmission frequencies, and the signal processor of Fig. 2 is but one embodiment of a signal processor. Other embodiments can  
30 receive and monitor available programming in transmission frequencies other than radio and television frequencies through the addition of one or more other signal decoders such as that of Fig. 2C described below. Embodiments can receive one or more fixed frequencies continuously at one or  
35 more decoders that monitor for available programming. For

34

certain applications, one particular embodiment (hereinafter, "signal processor alternative #1") can be configured to receive only other inputs at buffer/comparator, 8, in which case said embodiment has no oscillator, 6; switch, 1; mixers, 5 2 and 3; or decoders, 30 or 40. For other particular applications, another particular embodiment (hereinafter, "signal processor alternative #2") can be configured to receive only inputs at buffer/comparator, 14, in which case said embodiment has only buffer/comparator, 14; recorder, 16; 10 clock, 18; and the control device apparatus associated with controller, 20. Other signal processor embodiments will become apparent in this full specification. Which particular embodiment of signal processor is preferred at any given subscriber station depends on the particular communications 15 requirements of said station.

#### SIGNAL DECODERS

Signal decoder apparatus such as decoder, 203, in Fig. 1 and decoders, 30 and 40, in Fig. 2 are basic in the unified 20 system of this invention.

Fig. 2A shows a TV signal decoder that detects signal information embedded in an inputted television frequency, renders said information into digital signals that subscriber station apparatus can process, identifies the particular 25 apparatus to which said signals are addressed, and outputs said signals to said apparatus. Decoder, 203, in Fig. 1 is one such TV signal decoder; decoder, 30, in Fig. 2 is another.

In Fig. 2A, a selected frequency is inputted at a 30 fixed frequency to said decoder at filter, 31, which defines the particular channel of interest to be analyzed. The television channel signal then passes to a standard amplitude demodulator, 32, which uses standard demodulator techniques, well known in the art, to define the television base band 35 signal. This base band signal is then transferred through

35

separate paths to three separate detector devices. The apparatus of these separate paths are designed to act on the particular frequency ranges in which embedded signal information may be found. The first path, designated A, 5 detects signal information embedded in the video information portion of said television channel signal. Path A inputs to a standard line receiver, 33, well known in the art. Said line receiver, 33, receives the information of one or more of the lines normally used to define a television picture. It 10 receives the information only of that portion or portions of the overall video transmission and passes said information to a digital detector, 34, which acts to detect the digital signal information embedded in said information, using standard detection techniques well known in the art, and 15 inputs detected signal information to controller, 39, which is considered in greater detail below. The second path, designated B, detects signal information embedded in the audio information portion of said television channel signal. Path B inputs to a standard audio demodulator, 35, which uses 20 demodulator techniques, well known in the art, to define the television audio transmission and transfers said audio information to high pass filter, 36. Said filter, 36, defines and transfers to digital detector, 37, the portion of said audio information that is of interest. The digital 25 detector, 37, detects signal information embedded in said audio information and inputs detected signal information to controller, 39. The third path, designated C, inputs the separately defined transmission to a digital detector, 38, which detects signal information embedded in any other 30 information portion of said television channel signal and inputs detected signal information to controller, 39. Line receiver, 33; high pass filter, 36; detectors, 34, 37, and 38; and controller, 39, all operate under control of controller, 39, and in preprogrammed fashions that may be 35 changed by controller, 39.

36

Fig. 2B shows a radio signal decoder that detects and processes signal information embedded in an inputted radio frequency. Decoder, 40, in Fig. 2 is one such radio signal decoder. A selected frequency of interest is inputted 5 at a fixed frequency to standard radio receiver circuitry, 41, which receives the radio information of said frequency using standard radio receiver techniques, well known in the art, and transfers said radio information to radio decoder, 42. Radio decoder, 42, decodes the signal information 10 embedded in said radio information and transfers said decoded information to a standard digital detector, 43. Said detector, 43, detects the binary signal information in said decoded information and inputs said signal information to controller, 44, discussed more fully below. Circuitry, 41; 15 decoder, 42; and detector, 43, all operate under control of controller, 44, and in predetermined fashions that may be changed by controller, 44..

Fig. 2C shows a signal decoder that detects and processes signal information embedded in a frequency other 20 than a television or radio frequency. A selected other frequency (such as a microwave frequency) is inputted to appropriate other receiver circuitry, 45, well known in the art. Said receiver circuitry, 45, receives the information of said frequency using standard receiver techniques, well 25 known in the art, and transfers said information to an appropriate digital detector, 46. Said detector, 46, detects the binary signal information in said information and inputs said signal information to controller, 47, considered more fully below. Circuitry, 45, and detector, 46, operate under 30 control of controller, 47, and in predetermined fashions that may be changed by controller, 47.

Each decoder is controlled by a controller, 39, 44, or 47, that has buffer, microprocessor, ROM, and RAM capacities. Said buffer capacity of controller, 39, 44, or 47, includes 35 capacity for receiving, organizing, and storing simultaneous

37

inputs from multiple sources while inputting information, received and stored earlier, to said microprocessor capacity of controller, 39, 44, or 47. Said microprocessor capacity of controller, 39, 44, or 47, is of a conventional type, well known in the art, and is specifically designed to have particular register memories, discussed more fully below, including register capacity for detecting particular end of file signals in inputted information. The ROM capacity of controller, 39, 44, or 47, contains microprocessor control instructions of a type well known in the art and includes EPROM capacity. Said ROM and/or said EPROM may also contain one or more digital codes capable of identifying its controller, 39, 44, or 47, uniquely and/or identifying particular subscriber station functions of said controller, 39, 44, or 47. The RAM capacity of controller, 39, 44, or 47, constitutes workspace that the microprocessor of said controller, 39, 44, or 47, can use for intermediate stages of information processing and may also contain microprocessor control instructions. Capacity exists at said controller, 39, 44, or 47, for erasing said EPROM, and said RAM and said EPROM are reprogrammable.

Controller, 39, 44, or 47, is preprogrammed to receive units of signal information, to assemble said units into signal words that subscriber station apparatus can receive and process, and to transfer said words to said apparatus. In each decoder, the controller, 39, 44, or 47, receives detected digital information from the relevant detector or detectors, 34, 37, 38, 43, and 46. Upon receiving any given instance of signal information, controller, 39, 44, or 47, is preprogrammed to process said information automatically. Controller, 39, is preprogrammed to discard received duplicate, incomplete, or irrelevant information; to correct errors in retained received information by means of forward error correction techniques well known in the art; to convert, as may be required, the corrected information, by

38

means of input protocol techniques well known in the art, into digital information that subscriber station apparatus can receive and process; to modify selectively particular corrected and converted information in a predetermined fashion or fashions; to identify in a predetermined fashion or fashions subscriber station apparatus to which said signal information should be transferred; and to transfer said signals to said apparatus. Said controller, 39, 44, or 47, has one or more output ports for communicating signal information to said apparatus.

Controller, 39, 44, or 47, has capacity for identifying more than one apparatus to which any given signal should be transferred and for transferring said signal to all said apparatus. It has capacity for recording particular signal information in particular register memory and for transferring a given signal to one apparatus, modifying it and transferring it to a second apparatus, and modifying it again and transferring it to a third apparatus.

As described above, said controller, 39, 44, or 47, controls particular apparatus of its signal decoder and has means for communicating control information to said apparatus. Said controller, 39, 44, or 47, also has means for communicating control information with a controller, 20, of a signal processor, 26. (Said communicating means is shown clearly in Fig. 2D which is discussed below.) Via said communicating means and under control of instructions and signals discussed more fully below, said controller, 20, has capacity to cause information at said EPROM to be erased and to reprogram said microprocessor control instructions at said RAM and said EPROM.

#### THE SIGNAL PROCESSOR SYSTEM

Signal processing apparatus and methods involve an extended subscriber station system focused on the signal processor. Said system includes external signal decoders.

39

Fig. 2D shows one embodiment of a signal processing system. Said system contains signal processor, 26, and external decoders, 27, 28, and 29. Each said external decoder may be a TV signal decoder (Fig. 2A) or a radio  
5 signal decoder (Fig. 2B) or an other signal decoder (Fig. 2C) depending on the nature of the selected frequency inputted. As Fig. 2D shows, each decoder, 27, 28, and 29, receives one selected frequency and has capacity for transferring detected, corrected, converted, and possibly modified signals  
10 to signal processor, 26, at buffer/comparator, 8, and also to other station apparatus. Each decoder, 27, 28, and 29, also has capacity for transferring detected, corrected, converted, and possibly modified monitor information to signal processor, 26, at buffer/comparator, 14. As Fig. 2D shows,  
15 controller, 20, has capacity to control all decoder apparatus, 27, 28, 29, 30, and 40. Controller, 20, has capacity to preprogram (or reprogram) all said decoder apparatus, 27, 28, 29, 30, and 40, and thereby controls the fashions of detecting, correcting, converting, modifying,  
20 identifying, transferring, and other functioning of said decoders.

Not every installed decoder in said signal processor system requires all the apparatus and system capacity of Figs. 2A, 2B, and 2C. For example, because a television  
25 base band signal is inputted to decoder, 203 of Fig. 1, said decoder does not require filter, 31, and demodulator, 32, of Fig. 2A. Likewise, because decoders, 30 and 40 of Fig. 2, transfer signals only to buffer/comparator, 8, said decoders do not require capacity to transfer signals to any other  
30 apparatus, and controllers, 39 and 44, of said decoders are preprogrammed only to identify whether or not any given signal should be transferred to buffer/comparator, 8. The precise apparatus and operating fashions of any given decoder is commensurate with the operating requirements of the  
35 installation and subscriber station of said decoder.

40

Fig. 2D shows decoders, 27, 28, and 29, communicating monitor information to buffer/comparator, 14, of signal processor, 26, by means of bus, 13. Said bus, 13, communicates information in a fashion well known in the art, and said decoders, 27, 28, and 29, gain access to the shared transmission facility of said bus, 13, using access methods, such as contention, that are well known in the art. Controllers, 12 and 20 of Fig. 2, 39 of Fig. 2A, 44 of Fig. 2B, and 47 of Fig. 2C, all have capacity to transfer signal information by bus means. Buffer/comparator, 8 and 14, and controller, 12, of Fig. 2 all have capacity to receive other input information from bus means. Furthermore, all apparatus of Fig. 2 and of Fig. 2D can have capacity to communicate control information by one or more bus means.

15

#### INTRODUCTION TO THE SIGNALS OF THE INTEGRATED SYSTEM

The signals of the present invention are the modalities whereby stations that originate programming transmissions control the handling, generating, and displaying of programming at subscriber stations.

20

(The term, "SPAM," is used, hereinafter, to refer to signal processing apparatus and methods of the present invention.)

SPAM signals control and coordinate a wide variety of subscriber stations. Said stations include so-called "local affiliate" broadcast stations that receive and retransmit single network transmissions; so-called "cable system headends" that receive and retransmit multiple network and local broadcast station transmissions; and so-called "media centers" in homes, offices, theaters, etc. where subscribers view programming. (Hereinafter, stations that originate broadcast transmissions are called "original transmission stations," stations that receive and retransmit broadcast transmissions are called "intermediate transmission stations", and stations where subscribers view programming

35

41

are called "ultimate receiver stations.")

At said stations, SPAM signals address, control, and coordinate diverse apparatus, and the nature and extent of the apparatus installed at any given station can vary greatly. SPAM signals control not only various kinds of receivers and tuners; transmission switches and channel selectors; computers; printers and video and audio display apparatus; and video, audio, and digital communications transmission recorders but also signal processor system apparatus including decoders; decryptors; control signal switching apparatus; and the communications meters, called signal processors, of the present invention. Besides apparatus for communicating programming to viewers, SPAM signals also address and control subscriber station control apparatus such as, for example, furnace control units whose operations are automatic and are improved with improved information and subscriber station meter apparatus such as, for example, utilities meters that collect and transmit meter information to remote metering stations.

The information of SPAM signals includes data, computer program instructions, and commands. Data and program instructions are often recorded in computer memories at subscriber stations for deferred execution. Commands are generally for immediate execution and often execute computer programs or control steps in programs already in process. Often said data, programs, and commands control subscriber station apparatus that automatically handle, decrypt, transmit, and/or present program units of conventional television, radio, and other media.

In combined medium communications, SPAM signals also control subscriber station apparatus in the generating and combining of combined medium programming. At ultimate receiver stations, particular combined medium commands and computer programs cause computers to generate user specific programming and display said programming at television sets,

42

speaker systems, printers, and other apparatus.

(Hereinafter, instances of computer program information that cause ultimate receiver station apparatus to generate and display user specific information are called "program instruction sets.") At intermediate transmission stations, other commands and computer programs cause computers to generate and transmit program instruction sets.

(Hereinafter, instances of computer program information that cause intermediate transmission station apparatus to generate program instruction set information and/or command information are called "intermediate generation sets.")

In combined medium communications, particular SPAM commands control the execution of intermediate generation sets and program instruction sets and the transmission and display of information generated by said sets. Whether said commands control apparatus at intermediate transmission stations, ultimate receiver stations, or both, the function of said commands is to control and synchronize disparate apparatus efficiently in the display of combined medium programming at ultimate receiver stations. (Accordingly, all said commands are called "combining synch commands" in this specification.) Most often, combining synch commands synchronize steps of simultaneous generating of station specific information at pluralities of stations and/or steps of simultaneous combining at pluralities of stations (which steps of combining are, more specifically, steps of simultaneous transmitting at each station of said pluralities of separate information into combined transmissions), all of which steps are timed to control simultaneous display of user specific combined medium information at each station of pluralities of ultimate receiver stations.

The present invention provides a unified signal system for addressing, controlling, and coordinating all said stations and apparatus. One objective of said system is to control diverse apparatus in in the speediest and most

43

efficient fashions. A second objective is to communicate control information in forms that have great flexibility as regards information content capacity. A third objective is to communicate information in compact forms, thereby  
5 maximizing the capacity of any given transmission means to communicate signal information.

Yet another objective is expandability. As the operating capacities of computer hardware have grown in recent decades, increasingly sophisticated software systems  
10 have been developed to operate computers. Often incompatibilities have existed between newly developed operating system software and older generations of computer hardware. It is the objective of the system of signal composition of the present invention to have capacity for  
15 expanding to accommodate newly developed subscriber station hardware while still serving older hardware generations. In practice this means that the unified system of signals does not consist, at any one time, of one fixed and immutable version of signal composition. Rather it is a family of  
20 compatible versions. At any given time, some versions communicate signal information to only the newest or most sophisticated subscriber station apparatus while at least one version communicates to all apparatus. Accordingly, this specification speaks of "simple preferred embodiments" and  
25 "the simplest preferred embodiment" rather than just one preferred embodiment. How the various versions and embodiments relate to and are compatible with one another is made clear below.

30 THE COMPOSITION OF SIGNAL INFORMATION ... COMMANDS,  
INFORMATION SEGMENTS, AND PADDING BITS

SPAM signals contain binary information of the sort well known in the art including bit information required for error correction using forward error correction techniques,  
35 well known in the art, in point to multi-point

44

communications; request retransmission techniques, well known in the art, in point to point communications; and/or other error correction techniques, as appropriate.

Fig. 2E shows one example of the composition of signal information (excluding bit information required for error detection and correction). The information in Fig. 2E commences with a header which is particular binary information that synchronizes all subscriber station apparatus in the analysis of the information pattern that follows. Following said header are three segments: an execution segment, a meter-monitor segment, and an information segment. As Fig. 2E shows, the header and execution and meter-monitor segments constitute a command.

A command is an instance of signal information that is addressed to particular subscriber station apparatus and that causes said apparatus to perform a particular function or functions. A command is always constituted of at least a header and an execution segment. With respect to any given command, its execution segment contains information that specifies the apparatus that said command addresses and specifies a particular function or functions that said command causes said apparatus to perform. (Hereinafter, functions that execution segment information causes subscriber station apparatus to perform are called "controlled functions.")

Commands often contain meter-monitor segments. Said segments contain meter information and/or monitor information, and the information of said segments causes subscriber station signal processor systems to assemble, record, and transmit meter records to remote billing stations and monitor records to remote ratings stations in fashions that are described more fully below.

Particular commands (called, hereinafter, "specified condition commands") always contain meter-monitor segments. Said commands cause addressed apparatus to perform controlled

45

functions only when specified conditions exist, and meter-monitor information of said commands specifies the conditions that must exist.

In simple preferred embodiments, at any given time the number of binary information bits in any given instance of header information is a particular constant number. In other words, every header contains the same number of bits. In the simplest preferred embodiment, said constant number is two, all headers consist of two bits binary information, and commands are identified by one of three binary headers:

- 10 - a command with an execution segment alone;
- 00 - a command with execution and meter-monitor segments;  
and
- 01 - a command with execution and meter-monitor segments  
that is followed by an information segment.

20

Execution segment information includes the subscriber station apparatus that the command of said segment addresses and the controlled functions said apparatus is to perform. ("ITS" refers, hereinafter, to intermediate transmission station apparatus, and "URS" refers to ultimate receiver station apparatus.) Examples of addressed apparatus include:

- ITS signal processors (in 71 in Fig. 6),
- ITS controller/computers (73 in Fig. 6),
- URS signal processors (200 in Fig. 7),

355

46

URS microcomputers (205 in Fig. 7),

URS printers (221 in Fig. 7), and

5        URS utilities meters (262 in Fig. 7).

Examples of controlled functions include:

10

Load and run the contents of the information segment.

Decrypt the execution segment using decryption key G.

15

Decrypt the execution and meter-monitor segments using  
decryption key J.

Commence the video overlay combining designated in the  
meter-monitor segment.

20

Modify the execution segment to instruct URS  
microcomputer, 205, to commence overlay designated in  
meter-monitor segment, record the contents of the  
execution and meter-monitor segments, and transfer  
25        command to URS microcomputer, 205.

Print the contents of the information segment.

30

Record the contents of the execution and meter-monitor  
segments; transfer them to URS decryptors, 224, and  
execute the preprogrammed instructions that cause URS  
decryptors, 224, to commence decrypting with said  
contents as decryption key; execute preprogrammed  
instructions that cause URS cable converter boxes,  
35        222, to switch to cable channel Z; execute

47

preprogrammed instructions that cause URS matrix switches, 258, to configure its switches to transfer the input from converter boxes, 222, to decryptors, 224, and the output from decryptors, 224, to  
5 microcomputers, 205; modify the execution segment to instruct URS microcomputers, 205, to commence loading and executing the information received from URS decryptors, 224 via URS switches, 258.

10

Commands can address many apparatus and execute many controlled functions. The apparatus and functions listed here are only examples. Other addressable apparatus and controlled functions will become apparent in this full  
15 specification.

Execution segment information operates by invoking preprogrammed operating instructions that exist at each subscriber station apparatus that is addressed. For example, a command to URS microcomputers, 205, to load and run the  
20 contents of the information segment following said command causes each URS microcomputer, 205, to commence processing particular instructions for loading and running that are preprogrammed at each URS microcomputer, 205.

For each appropriate addressed apparatus and  
25 controlled function combination a unique execution segment binary information value is assigned. Said command to URS microcomputers, 205, to load and run is, for example, one appropriate combination and is assigned one particular binary value that differs from all other execution segment  
30 information values. In the assignment process, no values are assigned to inappropriate combinations. For example, URS signal processors, 200, have no capacity to overlay, and no execution segment information value exists to cause URS signal processors, 200, to overlay.

35

For any given command, the execution segment

48

information of said command invokes, at each relevant subscriber station apparatus, the preprogrammed operating instructions uniquely associated with its particular binary value in particular comparing and matching fashions that are 5 described more fully below.

The determination of appropriate addressed apparatus and controlled function combinations takes into account the facts that different apparatus, at any given subscriber station, can be preprogrammed to interpret any given instance 10 of execution segment information differently and that subscriber station apparatus can be preprogrammed to automatically alter execution segment information. For example, if signal processors, 200, are preprogrammed to process commands received at controller, 12, differently from 15 commands received at buffer/comparator, 8, the assignment system can reduce the number of required binary values. As a more specific example, buffer/comparator, 8, receives a hypothetical command with a particular execution segment (e.g., "101110") which means "URS signal processors, 200, 20 decrypt the execution and meter-monitor segments using decryption key J." After being decrypted and transferred to controller, 12, the particular execution segment information that controller, 12, receives (e.g., "011011") means "URS microcomputers, 205, commence overlay designated in meter- 25 monitor segment." The controlled functions that signal processor, 200, performs are the same as those listed above in the example that begins, "Modify the ... ," and no separate binary value is necessary for invoking these controlled functions at URS microcomputers, 200.

30 The preferred embodiment includes one appropriate command (hereinafter called the "pseudo command") that is addressed to no apparatus and one command that is addressed to URS signal processors, 200, (hereinafter, the "meter command") but does not instruct said processors, 200, to 35 perform any controlled function. These commands are always

49

transmitted with meter-monitor segment data that receiver station apparatus automatically process and record. By transmitting pseudo command and meter command signals, transmission stations cause receiver station apparatus to  
5 record meter-monitor segment information without executing controlled functions. The pseudo command enables a so-called ratings service to use the same system for gathering ratings on conventional programming transmissions that it uses for combined media without causing combined media apparatus to  
10 execute controlled functions at inappropriate times (eg., combine overlays onto displays of conventional television programming). The meter command causes apparatus such as controller, 12, of Fig. 2D to transmit meter information to buffer/comparator, 14, without performing any controlled  
15 function.

In the preferred embodiment, at any given time the number of binary information bits in any given instance of execution segment information is a particular constant number. In other words, every execution segment contains the  
20 same number of bits. Said constant number is the smallest number of bits capable of representing the binary value of the total number of appropriate addressed apparatus and controlled function combinations. And each appropriate combination is assigned a unique binary value within the  
25 range of binary numbers thus defined.

Meter-monitor segments contain meter information and/or monitor information. Examples of categories of such information include:

30

meter instructions that instruct subscriber station meter apparatus to record particular meter-monitor segment information and maintain meter records of said information;

35

50

- origins of transmissions (eg., network source stations,  
broadcast stations, cable head end stations);
- dates and times;
- 5 unique identifier codes for each program unit (including  
commercials);
- codes that identify uniquely each combining in a given  
10 combined medium program unit;
- codes that identify the subject matter of a program unit;
- unique codes for programming (other than programming  
15 identified by program unit codes) whose use  
obligates users to make payments (eg., royalties  
and residuals); and
- unique codes that identify the sources and suppliers of  
20 computer data.

The categories listed here provide only examples. Other  
types of information can exist in meter information and/or in  
25 monitor information, as will become apparent in this full  
specification.

For each category of information, a series of binary  
bits (hereinafter, a "field" or "meter-monitor field") exists  
in the meter-monitor segment to contain the information. In  
30 any given category such as origins of transmissions, each  
distinct item such as each network source, broadcast, or  
cable head end station has a unique binary information code.  
In the preferred embodiment, the number of information bits  
in that category's meter-monitor field is the smallest number  
35 of bits capable of representing the binary value of the total

5/

number of distinct items. And the information code of each distinct item is within the range of binary numbers thus defined. In the preferred embodiment, date and time fields have sixteen bits.

5 Few commands require meter-monitor information of every information category. Often commands require no more than the identification codes of a specific combined medium program unit and of a specific combined medium combining within said program unit.

10 Because the amount of information in meter-monitor segments varies from command to command, in the preferred embodiment more than one format exists at any given time for meter-monitor segment information. For example, one meter-monitor segment may contain origin of transmission,  
15 transmission date and time, and program unit information. A second may contain program unit and combining identification information. The first is transmitted in a format of three specific fields. The second is transmitted in a different format. It is even possible for different formats to exist  
20 for the same meter-monitor field. For example, one instance of date and time information designates a particular day in a particular one hundred year period. Another designates a particular hour in a particular ninety day period.

Because the number of categories of meter-monitor  
25 information varies from one command to the next, the length of meter-monitor segments varies. Unlike execution segments which, at any given time, all contain the same number of information bits, the bit length of meter-monitor segments varies. One segment may contain five fields, totaling 275  
30 bits in length. Another may contain two fields and 63 bits. A third may contain three fields and 63 bits. Bit length is not necessarily tied to the number of fields. And at any given time, a number of different meter-monitor segment bit length alternatives exists.

35 In the preferred embodiment, each instance of a

52

meter-monitor segment includes a format field that contains information that specifies the particular format of the meter-monitor segment of said instance. Within said field is a particular group of binary information bits 5 (hereinafter, the "length token") that identifies the number of bits in a meter-monitor segment of said format. Each alternate length token has a unique binary information code. The number of information bits in each instance of a length token is the smallest number of bits capable of representing 10 the binary value of the total number of meter-monitor segment bit length alternatives. And the unique code of each different alternative is within the range of binary numbers thus defined.

In the preferred embodiment, each distinct meter- 15 monitor segment format (including each distinct field format) also has a unique binary information code. In cases where a given format is the only format that contains a given length token, the unique code of said token is sufficient to identify said format uniquely. For example, if a particular 20 format is the only format that is 197 binary bits long, information that said format is 197 bits long is sufficient information to identify said format uniquely. But two or more formats that contain the same length token information require additional binary information to distinguish them 25 uniquely. Thus the number of information bits in any given instance of a format field is the total of the number of bits in the length token plus the smallest number of bits capable of representing the number of formats that share in common the one particular length token datum that occurs most 30 frequently in different formats. And the format code of each distinct format is within the range of binary numbers thus defined except that only length token information exists in the bits of the length token.

Fig. 2F illustrates one instance of a meter-monitor 35 segment (excluding bit information required for error

53

detection and correction). Fig. 2F shows three fields totalling thirty sequential bits. The format field is transmitted first followed by two fields of nine and sixteen bits respectively, and the bits of the length token are the first bits of said format field. The SPAM system that uses said format field has capacity for no more than eight alternate meter-monitor segment lengths and thirty-two formats. A three bit length token can specify no more than eight length alternatives, and a five bit format field can specify no more than thirty-two. Said SPAM system has no fewer than five alternate lengths because four or fewer length alternatives would be represented in a length token of two or fewer bits. In said system, three or four formats share in common the particular length token that occurs most frequently in different formats. Two formats sharing the most commonly shared length token datum would be specified in one bit; five or more sharing said datum would be represented in three or more bits. Accordingly, the format field of Fig. 2F must represent at least eight alternate formats.

20 In the preferred embodiment, the bits of the length token are the first bits in each meter-monitor segment. In any given command containing meter-monitor information, said bits follow immediately after the last bit of the execution segment. The remaining bits of the format field are included in each meter-monitor segment in particular locations that lie within the format of the shortest meter-monitor segment (excluding bit information required for error detection and correction). Thus if the shortest meter-monitor segment (including the format field of said segment) is thirty two bits, the bits of the format field in every instance of a meter-monitor segment lie among the first thirty two bits of said segment.

30 Information segments follow commands and can be of any length. Program instruction sets, intermediate generation sets, other computer program information, and data (all of

54

which are organized in a fashion or fashions well known in the art) are transmitted in information segments. An information segment can transmit any information that a processor can process. It can transmit compiled machine language code or assembly language code or higher level language programs, all of which are well known in the art. Commands can execute such program information and cause compiling prior to execution.

A command with a "01" header is followed by an information segment. But a command with an "01" header is not the only instance of signal information that contains an information segment. In the simplest preferred embodiment, a fourth type of header is:

15

11 - an additional information segment transmission following a "01" header command and one or more information segments which additional segment is addressed to the same apparatus and invokes the same controlled functions as said "01" command.

20

An instance of signal information with a "11" header contains no execution segment or meter-monitor segment information. Said instance is processed, in fashions described more fully below, by subscriber station apparatus that receive said instance as if said instance contained the execution segment information of the last "01" header command received at said apparatus prior to the receipt of said instance.

In determining the composition of signal information in the preferred embodiment, the present invention must take into account the fact that most computer systems communicate information in signal words that are of a constant binary length that exceeds one bit. At present, most computer

35

55

information is communicated in so-called "bytes," each of which consists of eight digital bits. Failure to recognize this fact could result in incomplete signals and/or in erroneous processing in signal information. For example, Fig 5 2G shows a command with a header, an execution segment, and a meter-monitor segment, each of which is of particular bit length. However, the command of Fig. 2G is only twenty-one bits long. As Fig. 2G shows, said command constitutes two bytes of eight bits each with five bits are left over. In a 10 system that communicates information only in words that are multiples of eight, a signal whose information is represented in twenty-one information bits is incomplete. To constitute a complete communication, said signal must be transmitted in twenty-four bits. To the command of Fig. 2G, three bits must 15 be added.

In the preferred embodiment, at the original transmission station of any given signal transmission, particular bits are added at the end of any command that is not already a multiple of the particular signal word bit 20 length that applies in signal processor system communications at the subscriber stations to which said transmission is transmitted. (Hereinafter, said bits are called "padding bits.") Padding bits communicate no command information nor are padding bits part of any information segment. The sole 25 purpose of padding bits is to render the information of any given SPAM command into a bit length that is, by itself, complete for signal processor system communication. Padding bits are added to command information prior to the transmission of said information at said station, and all 30 subscriber station apparatus are preprogrammed to process padding bits. The particular number of padding bits that are added to any given command is the smallest number of bits required to render the bit length of said command into a multiple of said signal word bit length. Fig. 2H shows three 35 padding bits added at the end of the twenty-one command

56

information bits of the command of Fig 2G. to render the information of said command into a form that can be communicated in three eight-bit bytes.

In the preferred embodiment, the information of each  
5 information segment is composed and transmitted in a bit length that is, itself, exactly a multiple of the particular signal word bit length that applies in computer communications at said subscriber stations. The information of each information segment commences at the first  
10 information bit location of the first signal word of said segment and ends at the last information bit location of the last signal word. Each information segments follow a command or "11" header. More precisely, the first signal word of each information segment is the first complete signal  
15 word that follows the last information bit of said command or "11" header or the last padding bit following said command or "11" header if one or more padding bits follow.

As one example, Fig. 2I shows the information of Fig 2E organized in eight-bit bytes. While the information of  
20 the execution segment in Fig. 2I follows immediately after the header and the information of the meter-monitor segment follows immediately after the execution segment, the information of the information segment does not follow immediately after the meter-monitor segment. Rather three  
25 padding bits are inserted following the command information of Fig. 2I to complete the signal word in which the last bit of command information occurs, and the information of the information segment begins at the first bit of the first complete byte following said meter-monitor segment.

30 The method of the preferred embodiment for composing the information of SPAM signals has significant advantages.

In signal processing, speed of execution is often of critical importance, and the preferred embodiment has significant speed advantages. Most commands require the  
35 fastest possible processing. By minimizing the bit length of

57

headers, execution segments, and meter-monitor segments, the preferred embodiment provides compact information and control messages that are transmitted, detected, and executed, in general, in the fastest possible fashion.

5 In signal processing, flexibility of message structure is also of critical importance. The single, unified system of the present invention must have capacity for communicating to many different apparatus messages that vary greatly in complexity, length, and priority for speed of processing. By  
10 providing first priority segment capacity--in the simplest preferred embodiment, execution segments--that is short, rigid in format, and can communicate information to many different addressed apparatus, the preferred embodiment provides capacity to communicate a select number of high  
15 priority control messages to many alternate apparatus in the fastest possible time. By providing intermediate priority segment capacity--in the simplest preferred embodiment, meter-monitor segments--that is flexible in length, format, and information content, the preferred embodiment provides  
20 more flexible capacity to communicate control messages of slightly lower priority. By providing lowest priority segment capacity--in the simplest preferred embodiment, information segments--that can contain any binary information and be any length, the preferred embodiment provides complete  
25 flexibility to communicate any message that can be represented in digital information to any apparatus at the lowest processing priority. By transmitting message components in their order of priority--in the simplest preferred embodiment, headers and execution segments then  
30 meter-monitor segments then information segments--the preferred embodiment enables priority message instructions to affect subscriber station operations in the fastest possible fashion. By providing capacity for alternating the structure of individual messages--here alternate header capacity--so  
35 that individual control messages can be constituted only of

58

the highest priority information or high and intermediate priority information or can be focused on the lowest priority, the preferred embodiment provides additional valuable flexibility.

5       Speed and flexibility are essential considerations not only in the composition of individual messages but also in the composition of message streams. In this regard, the use of "II" headers in the preferred embodiment brings valuable benefits.

10       Often in the course of a combined medium presentation, a series of control messages is transmitted each of which contains an information segment, addresses the same apparatus (for example, URS microcomputers, 205), and causes said apparatus to invoke the same controlled function or functions  
15 (for example, "load and run the contents of the information segment"). Often, interspersed in said series, are other control messages that address said apparatus, contain no information segments, and cause said apparatus to invoke other controlled functions (for example, "commence the video  
20 overlay combining designated in the meter-monitor segment"). By including capacity whereby, without containing execution or meter-monitor information, a given message can cause information segment information to be processed at subscriber station apparatus just as preceding information segment  
25 information was processed, the present invention increases processing efficiency. Because no execution or meter-monitor segment is transmitted, more information segment information can be transmitted in a given period of time. Because no execution or meter-monitor segment is received and processed  
30 at subscriber stations, information segment information can be received and processed faster.

      In signal processing, efficiency in the control of subscriber station apparatus is yet another factor of critical importance. By composing lowest priority segment  
35 information--in the simplest preferred embodiment,

59

information of information segments--to commence at a bit location that subscriber station apparatus are preprogrammed to define as the first location of a signal word of the form that control said apparatus in processing and to continue to 5 a bit location that is the last location of a signal word of said form, the present invention communicates said information to said apparatus in a form that can commence the control functions communicated in said information immediately. Were information segment information 10 communicated in any form other than that of the preferred embodiment--more specifically, were said information to be in a length other than a whole number of signal words or to commence immediately after the command or header preceding said segment rather than at the first bit of a signal word-- 15 subscriber station apparatus would need to process said information into information of a form that could control said apparatus before the information of said segment could commence the particular control functions communicated in said information.

20 THE ORGANIZATION OF MESSAGE STREAMS ... MESSAGES, CADENCE INFORMATION, AND END OF FILE SIGNALS

All of the information transmitted with a given header is called a "message." Each header begins a message, and 25 each message begins with a header. More specifically, a message consists of all the SPAM information, transmitted in a given transmission, from the first bit of one header to the last bit transmitted before the first bit of the next header.

A SPAM message is the modality whereby the original 30 transmission station that originates said message controls specific addressed apparatus at subscriber stations. The information of any given SPAM transmission consists of a series or stream of sequentially transmitted SPAM messages.

Each instance of a header synchronizes all subscriber 35 station apparatus in the analysis of the internal structure

60

of the message that follows.

However, for the unified system of the present invention to work, subscriber station apparatus must have capacity for distinguishing more than the internal structure of individual messages. Said apparatus must also have capacity for processing streams of SPAM messages and distinguishing the individual messages in said streams from one another. More precisely, said apparatus must have capacity for processing streams of binary information that consist only of "0" and "1" bits and distinguishing which information, among said bits, is header information.

Cadence information which consists of headers, certain length tokens, and signals that are called "end of file signals" enables subscriber station apparatus to distinguish each instance of header information in any given message stream and, hence, to distinguish the individual messages of said stream. In the present invention, subscriber station apparatus are preprogrammed to process cadence information.

SPAM messages are composed of elements--headers, execution segments, meter-monitor segments, and information segments--whose bit lengths vary. SPAM apparatus determine the bit length of said elements in different fashions, and the particular fashion that applies to any given element relates to the priority of said element for subscriber station speed of processing. First priority segment information has the highest priority for speedy processing and is of fixed binary bit length. A SPAM header is one example of a first priority segment. An execution segment is another example. Intermediate priority segment information has lower priority, varies in bit length, but contains internal length information. A Meter-monitor segment is one example of an intermediate priority segment. Lowest priority segment information has the lowest priority, varies in length, and contains no internal information for determining segment length. Each information segment is an example of a

6/

lowest priority segment.

For a message that is constituted only of first priority segments, the information of the header is sufficient to distinguish not only the structure of the message but also the location of the next header. In the simplest preferred embodiment, a message with a "10" header is one example of a message constituted only of first priority segments. Commands with "10" headers consist of header information and execution segment information. At any given time, all instances of header information are of one constant length, and all instances of execution segment information are of a second constant length. Thus all "10" commands are, themselves, of a particular header+exec constant length, said header+exec constant being the sum of said one constant plus said second constant. Because "10" messages have constant length and header information always occurs at a specific location in every instance of message information, by preprogramming subscriber station apparatus with information of said header+exec constant, the unified system of the present invention enables subscriber station apparatus to automatically identify the last command information bit of "10" messages. Said bit is always the bit that is located a particular quantity of bits after the first header bit which particular quantity equals said header+exec constant minus one. Being able to locate said last bit, said apparatus can automatically locate the next instance of header information in a fashion described below.

For messages whose elements include intermediate priority segment information but no lowest priority segment information, the information of said messages is also sufficient to distinguish message structure and the location of the next header. In the simplest preferred embodiment, each message associated with an "00" header is one such message. Messages with "00" headers consist of header and execution segment information that are, together, of said

62

header+exec constant length plus meter-monitor segment information that contains length token information. By preprogramming subscriber station apparatus with information for processing length token information, the present  
5 invention enables said apparatus to determine the particular information bit, following any instance of a "00" header, that is the last bit of the command of said header. Said bit is always the bit that is located a particular quantity of bits after the first header bit which quantity equals said  
10 header+exec constant minus one plus the particular preprogrammed quantity that said apparatus associates, in a preprogrammed fashion described more fully below, with the particular length token of said instance. By locating said last bit, said apparatus can automatically locate the next  
15 instance of header information in the fashion described below.

For messages whose elements include lowest priority segment information, particular end of lowest priority segment information is required to distinguish full message  
20 structure and the location of the next header. In the simplest preferred embodiment, each message associated with a "01" or a "11" contains an information segment header and is one such message. Information segments vary in length, and no internal information of a command or information segment  
25 enables subscriber station apparatus to determine the length of an information segment. Thus distinctive end of file signals are required to communicate the locations of the ends of information segments to subscriber station apparatus. In the present invention, each end of file signal is transmitted  
30 immediately after the end of an information segment; said signal is part of the information of the message in which said segment occurs; and said signal is located at the end of said message. By preprogramming subscriber station apparatus to detect and process end of file signals in a fashion  
35 described more fully below, the present invention enables

63

said apparatus to determine not only the particular information bit, following any instance of a "01" or "11" header, that is the last bit of the information segment of the message of said header but also the particular  
5 information bit, following said header, that is the last bit of said message. By locating said last bit of said message, said apparatus can automatically locate the next instance of header information in the fashion described below.

At any given time, subscriber station apparatus are  
10 preprogrammed to process only one distinct signal as an end of file signal. In order for said apparatus to distinguish an instance of said signal from all other signal information, an end of file signal must differ distinctly from all other information. Signal information, especially information  
15 transmitted in an information segment, can vary greatly in composition. Accordingly, to be distinctive, an end of file signal must be long and complex to detect.

An end of file signal consists of a particular sequence of bits of binary information. In the preferred  
20 embodiment each bit is identical to every other bit; that is, disregarding error correction information, an end of file signal consists of a sequence of "1" bits (eg. "11111111") or "0" bits (eg. "00000000"). In the preferred embodiment, end of file signals are composed of "1" bits rather than "0"  
25 bits. Zero is a value that occurs frequently in data and in mathematics, and however many bits may occur in a binary data word that consists of a series of "0" bits, the numeric value of said word remains zero. Numeric values that are represented in binary form by a sequence of "1" bits,  
30 especially a sequence that is long, occur in data and mathematics far less frequently than zero. Thus the preferred composition bit is "1" because the chance of data being joined in a given signal in such a way that two or more instance of information combine inadvertently and create the  
35 appearance of an end of file signal is far smaller if the

64

preferred bit is "1" than if it is "0". (Hereinafter, the preferred binary end of file signal composition bit, "1", is called an "EOFS bit," and for reasons that are explained below, the alternate binary bit, "0", is called a "MOVE 5 bit.")

In the preferred embodiment, the length of said sequence (disregarding error correction information) is the minimum reasonable length necessary to distinguish said sequence from all other sequences of transmitted signal 10 information of said length. In the preferred embodiment, the number of bits in said sequence is greater than the number of information bits in the data words that subscriber station computers use to process data. At present, most computers are so-called "thirty-two bit machines" that process 15 information in four-byte data words, and some high precision microprocessors such as the 8087 mathematics coprocessor distributed by the Intel Corporation of Santa Clara, California, U.S.A. process information internally in eighty bit registers which means that they process in 10-byte data 20 words. Thus said sequence may be greater than eighty bits long and is probably greater than thirty-two bits. Also in the preferred embodiment, said sequence uses the full information capacity of the signal words used to communicate said sequence at subscriber stations. In computer systems 25 that communicate information in eight-bit bytes, forty bits is the number of bits in the sequence next larger than thirty-two bits that uses the full communication capacity of the signal words in which it is communicated, and eighty-eight is the number of bits in the sequence next larger than 30 eighty bits. In the preferred embodiment, at any given time alternate end of file signal lengths exist. One potential end of file signal length can be forty (40) bits which is five bytes of EOFS bits. Another can be eighty-eight (88) bits which is eleven bytes of EOFS bits. Which end of file 35 signal is used for any given transmission depends on the

65

nature of the information of the transmission in which said signal occurs and the apparatus to which said transmission is transmitted.

Being the minimum "reasonable" length means that an instance of said sequence may actually be generated, in the system of the preferred embodiment, which instance is generated as information of a command or an information segment rather than an end of file signal. Were the information of said instance to be embedded in a SPAM transmission of said system and transmitted, said instance would cause erroneously processing at subscriber station apparatus by causing itself to be detected as an end of file signal and information transmitted subsequent to said instance to be interpreted as a new SPAM message. To prevent such erroneous processing, in the preferred embodiment, after the initial generation of any given instance of SPAM message information (not including end of file signal information) and before the embedding and transmitting of said instance, said information is transmitted through an apparatus, called an "EOFS valve," that detects end of file signals and is described below. If said valve detects in said information particular information that constitutes an end of file signal, before being embedded and transmitted, the binary information of said instance is rewritten, in a fashion well known in the art that may be manual, to cause substantively the same information processing at subscriber stations without containing an instance of information that is identical to the information of an end of file signal. (Hereinafter, such pre-transmission processing of a message is called a "pre-transmission evaluation.")

Fig. 2I shows a series of connected rectangles and depicts one instance of a stream of SPAM messages. Each rectangle represents one signal word of binary information. Fig. 2I shows a series of three messages. Each message is composed in a whole number of signal words. The first

66

message consists of a command followed by padding bits followed by an information segment followed by an end of file signal. The form of the command, padding bits, and the first information segment bits of said message is identical to the  
5 form of the information of Fig. 2E, given eight-bit bytes as the signal words of Fig. 2I. The second message consists of a command followed by padding bits. The form of said second message is identical to the form of the information of Fig. 2H, given eight-bit bytes as the signal words of Fig. 2I.  
10 The third message consists of a command alone. The form of said third message is identical to the form of the information of Fig. 2J, given eight-bit bytes as the signal words of Fig. 2I. Fig. 2J shows a message that is composed just of a "10" header and an execution segment. Said  
15 execution segment contains the same number of binary bits that the executions segments of Figs. 2E and 2H contain. Said header and execution segment of Fig. 2J fill one byte of binary information precisely, and given the signal word of an eight-bit byte, no padding bits are required in the message  
20 of Fig. 2J. Fig. 2H does not show an instance of a message that starts with a "11" header. Were it to do so, said message would be comprised of said header followed by six padding bits, given eight-bit bytes as the signal words of Fig. 2I, followed by an information segment, like the  
25 information segment of the first message of Fig. 2H, followed by an end of file signal, like the end of file signal of said first message.

As Fig. 2I shows, in any given SPAM transmission, no binary information separates the binary information of one  
30 SPAM message from the next message. As soon as the information of one SPAM message ends (including all error correction information associated with said information), the next received binary information is information of the next message. Because the first information bits (as distinct  
35 from error correction bits) of any given SPAM message

67

constitute the header information of said message, subscriber station apparatus locate the next instance of header information after any given message by locating the last information bit of the last signal word of said message.

5 Automatically the first information bits that follow said last bit and total in number the particular number of bits in an instance of header information constitute the next instance of header information.

Subscriber station apparatus locate the last  
10 information bit of any given SPAM message in one of two fashions. One fashion applies to messages that do not end with end of file signals. The other applies to messages that do. The header information of any given message determines which fashion applies for said message.

15 Messages that are constituted only of first priority segment elements and messages whose elements include intermediate priority segment information but no lowest priority segment information do not end with end of file signals. In the preferred embodiment, the header information  
20 of any given one of said messages cause subscriber station apparatus to execute particular preprogrammed locate-last-message-bit instructions at a particular time. In the simplest preferred embodiment, such messages begin with "10" or "00" headers.

25 Receiving any given instance of said header information causes subscriber stations processing message information of said instance to execute said locate-last-message-bit instructions after locating the last segment information bit of said instance and upon completing the  
30 processing of the segment information of said instance. (The fashions whereby subscriber station apparatus locate the last command information bit of any given instance of a message with a "10" or a "00" header are described above.) In a fashion that is described more fully below, said locate-last-  
35 message-bit instructions cause said apparatus to determine

68

whether the signal word in which said last segment information bit occurs contains one or more MOVE bits. If said signal word contains MOVE bit information, the last information bit of said signal word is the last information bit of said message. If said signal word does not contain MOVE bit information, the the last information bit of said message is last information bit of the next signal word immediately following said signal word in which said last segment information bit occurs. (For reasons that relate to detecting end of file signals and are discussed more fully below, in the preferred embodiment a complete signal word of padding bits is transmitted after any given instance of a signal word that contains no MOVE bit information and in which occurs the last bit of command information of the message of said instance.)

Messages that contain lowest priority segment information end with end of file signals, and the header information of said messages do not cause subscriber station apparatus to execute particular preprogrammed locate-last-message-bit instructions. End of file signals define the ends of messages that contain lowest priority segment information. In the simplest preferred embodiment, such messages begin with "10" or "00" headers. The last information bit of the end of file signal immediately following any given "10" or "00" header information message is the last information bit of the message of said "10" or "00" header, and subscriber station apparatus are preprogrammed to locate said bit in a fashion that is described below.

After locating any given instance of a last information bit of a message, subscriber station apparatus are preprogrammed to process automatically as header information the first information bits, following said bit, that are in number the particular number of bits in an instance of header information.

69

In this fashion, cadence information--header information, the length tokens of messages that contain intermediate priority segment information but no lowest priority segment information, and end of file signals--  
5 enables subscriber station apparatus to distinguish each instance of header information--and, hence, each message--in any given stream of SPAM messages.

#### DETECTING END OF FILE SIGNALS

10 In the present invention, any microprocessor, buffer/comparator, or buffer can be adapted and preprogrammed to detect end of file signals. At any given SPAM apparatus that is so adapted and preprogrammed, particular dedicated capacity exists for said detecting. Said capacity includes  
15 standard register memory or RAM capacity, well known in the art, including three particular memory locations for comparison purposes, one particular memory location to serve as a counter, and three so-called "flag bit" locations to hold particular true/false information. (Hereinafter, said  
20 three particular memory locations, said one particular memory location, and said three flag bit locations are called the "EOFS Word Evaluation Location," "EOFS Standard Word Location," and "EOFS Standard Length Location"; the "EOFS WORD Counter"; and the "EOFS WORD Flag," "EOFS Empty Flag,"  
25 and "EOFS Complete Flag" all respectively.) All operating instructions required to control said memory or RAM capacity in detecting end of file signals are preprogrammed as so-called "firmware" at said apparatus. (In this specification, said dedicated capacity is called an "EOFS valve" because, in  
30 addition to detecting end of file signals, said capacity also regulates the flow of SPAM information in fashions that are described more fully below.)

At any given EOFS valve, the EOFS Word Evaluation Location and EOFS Standard Word Location are conventional  
35 dynamic memory locations' each capable of holding one full

70

signal word of binary information. The EOFs Standard Length Location and the EOFs WORD Counter are each conventional dynamic memory locations capable of holding, at a minimum, eight binary bits--that is, one byte--of information. The 5 EOFs WORD Flag, EOFs Empty Flag, and EOFs Complete Flag are each conventional dynamic memory locations capable of holding, at a minimum, one bit of binary information.

At any given time, said valve holds particular information. At said EOFs Word Evaluation Location is one 10 signal word of received SPAM information. At said EOFs Standard Word Location is one signal word of EOFs bits. (Hereinafter, one signal word of EOFs bits is called an "EOFs WORD.") At said EOFs Standard Length Location is information of the total number of EOFs WORDs in the particular end of 15 file signal that applies at said time on the particular transmission received at said valve. Information of the decimal value, eleven, is at said Standard Length Location unless information of a number is placed at said Location in a fashion described below. At the EOFs WORD Counter is 20 information of the number of EOFs WORDs that said valve has received in uninterrupted sequence. And all said Flag locations contain binary "0" or "1" information to reflect true or false conditions in relation to particular comparisons.

25 At any given time, any given EOFs valve receives inputted binary information of one selected SPAM transmission from one particular external transferring apparatus that is external to said valve. Said information consists of a series of discrete signal words. And said valve outputs 30 information to one particular external receiving apparatus.

Receiving any given signal word of said transmission, causes said EOFs valve to commence, in respect to said given signal word, a particular word evaluation sequence that is fully automatic. Automatically said valve places information 35 of said word at said EOFs Word Evaluation Location and

71

compares the information at said Location to the EOFs WORD information at said EOFs Standard Word Location. Whenever said comparison is made, resulting in a match causes said valve automatically to set the information of said EOFs WORD Flag to "0". (Resulting in a match means that said given signal word is an EOFs WORD and may be a part of an end of file signal.) Not resulting in a match causes said valve automatically to set the information of said EOFs WORD Flag to "1". Then automatically said valve determines the value of said information at said EOFs WORD Flag, in a fashion well known in the art, and executes one of two sets of word evaluation sequence instructions on the basis of the outcome of said determining.

One set, the process-EOFs-WORD instructions, is executed whenever the information at said EOFs WORD Flag indicates that said given signal word is an EOFs WORD. Determining a value of "0" at said EOFs WORD Flag causes said valve to execute said set. Automatically the instructions of said set cause said valve to retain count information of said given signal word by increasing the value of the information at said EOFs WORD Counter by an increment of one.

(Incrementing said Counter by one documents the fact that, in receiving said given signal word, said valve has received, in uninterrupted sequence, one signal word that may be part of an end of file signal more than it had received before it received said given signal word.) Then automatically said valve compares the information at said EOFs WORD Counter to the information at said EOFs Standard Length Location.

Resulting in a match causes said valve automatically to set the information of said EOFs Complete Flag to "0". (A match of the information at said Counter with the information at said Location means that said given signal word is the last EOFs WORD in an uninterrupted sequence of EOFs WORDS that equals in length the length of an end of file signal; in other words, said match means that an end of file signal has

been detected.) Not resulting in a match causes said valve automatically to set the information of said EOFs Complete Flag to "1". (Not resulting in a match means said EOFs WORD is not the last EOFs WORD of an end of file signal 5 and that insufficient information has been received to determine whether or not said given signal word is part of an end of file signal.) Then automatically said valve determines the value of said information at said EOFs Complete Flag. Determining a value of "0" at said Flag, 10 which means that an end of file signal has been detected, causes said valve to operate in a fashion described more fully below. Determining a value of "1" at said Flag causes said valve, in a fashion described more fully below, to complete said word evaluation sequence, in respect to said 15 given signal word, without transferring any information of said given signal word to said external receiving apparatus.

The other set, the transfer-all-word-information instructions, is executed whenever the information at said EOFs WORD Flag indicates that said given signal word is not 20 an EOFs WORD. Whenever said valve detects a signal word that is not an EOFs WORD, detecting said word means not only that said word is not part of an end of file signal but also that any EOFs WORDs retained in an uninterrupted sequence immediately prior to said word are also not part of an end of 25 file signal. Determining a value of "1" at said EOFs WORD Flag causes said valve to execute said other set.

Automatically the instructions of said other set cause said valve to compare the information at said EOFs WORD Counter to particular zero information that is among the preprogrammed 30 information of said valve. (Not having been incremented by one under control of said process-EOFs-WORD instructions, said Counter contains information of the number of EOFs WORDs received in an uninterrupted sequence and retained at said valve at the time when said given signal word is received.) 35 Resulting in a match causes said valve automatically to set

73

the information of said EOFS Empty Flag to "0". (Resulting in a match means that said valve is empty of retained EOFS WORD information.) Not resulting in a match causes said valve automatically to set the information of said EOFS Empty Flag 5 to "1". (Not resulting in a match means that said valve contains information of EOFS WORDs that have not been transferred to said external receiving apparatus.) Then automatically said valve determines the value of said information at said EOFS Empty Flag. A determining of "1" 10 causes said valve to execute particular transfer-counted-information instructions that are not executed if the information at said Flag is "0". Under control of said instructions, said valve automatically outputs one instance of said EOFS WORD information at said EOFS Standard Word 15 Location a particular number of times which particular number is the numerical value of the information at said EOFS WORD Counter. (In so doing, said valve transfers information of all of the signal words received before said given signal word and not transferred to said external receiving 20 apparatus.) Then said transfer-counted-information instructions cause said valve to set the value at said EOFS WORD Counter to zero (to reflect that said valve is now empty of information of untransferred signal words). Then, whether or not said valve has executed said transfer-counted- 25 information instructions, said valve outputs information of said given signal word at said EOFS Word Evaluation Location and completes said word evaluation sequence, in respect to said given signal word.

Whenever said valve completes said word evaluation 30 sequence, in respect to any given signal word, said valve informs said external transferring apparatus (in a so-called "handshaking" fashion, well known in the art, or in such other flow control fashion as may be appropriate) that said valve is ready to receive next signal word information. 35 Whenever, after transferring a given signal word, said

74

apparatus is so informed, said apparatus transfers to said decoder the next signal word of said transmission immediately following said given signal word. Receiving said next signal word causes said valve to commence said word evaluation sequence, in respect to said next signal word. Automatically said valve places information of said next signal word at said EOFs Word Evaluation Location, and in so doing, overwrites and obliterates information of said given word at said EOFs Word Evaluation Location.

10 In this fashion, said valve processes each successive signal word to detect those particular uninterrupted series of EOFs WORDs that constitute end of file signals.

As described above, determining, under control of said process-EOFs-WORD instructions, that the value of the  
15 information at said EOFs Complete Flag is "0" means that an end of file signal has been detected. Determining, under control of said instructions, that said value is "0" causes said valve to execute particular complete-signal-detected instructions. Said instructions cause said valve to inform  
20 said external receiving apparatus of the presence of an end of file signal in a fashion that is the preprogrammed fashion of the microprocessor, buffer/comparator, or buffer of which said valve is an adapted component.

As one example of said fashion, for a buffer or  
25 buffer/comparator apparatus that operates under control of a controller to process received signal words and transfer signal information to a microprocessor (which may be a component of said controller), said instructions cause said valve to cause said apparatus to transmit particular EOFs-  
30 signal-detected information to said controller then to wait, in a waiting fashion well known in the art, for a control instruction from said controller. Said EOFs-signal-detected information causes said controller to determine, in a preprogrammed fashion, how to process the particular EOFs  
35 information at said valve and to transmit either a particular

75

transmit-and-wait instruction or a particular discard-and-wait instruction to said valve. (Examples of controller operations are presented below.) Said transmit-and-wait instruction causes said valve to transfer one complete end of file signal. More precisely, said instruction causes said valve automatically to output one instance of said EOFs WORD information at said EOFs Standard Word Location a particular number of times which particular number is the numerical value of the information at said EOFs Standard Length Location. Then automatically said valve sets the information at said EOFs WORD Counter to zero (thereby signifying that no EOFs WORDs are retained), completes said word evaluation sequence, in respect to the signal word of the information at said EOFs Word Evaluation Location, and transmits particular complete-and-waiting information to said controller. Alternatively, said discard-and-wait instruction causes said valve merely to set the information at said EOFs WORD Counter to zero (thereby discarding information of said end of file signal), to complete said word evaluation sequence, in respect to said signal word of the information at said EOFs Word Evaluation Location, and to transmit said complete-and-waiting information to said controller. Subsequently, said complete-and-waiting information causes said controller to transmit further instructions that control said apparatus and said valve in the processing of further information and the detecting of further end of file signals.

In the preferred embodiment, said EOFs-signal-detected information and said complete-and-waiting information are control signals that are transmitted by said valve and said apparatus to said controller as interrupts to the CPU of said controller.

An example illustrates the operation of an EOFs valve.

Fig. 2 shows one message that is of a particular command composed of a "00" header, an execution segment, and a meter-monitor segment. The information of said command

76

fills four bytes of binary precisely. The last bit of said meter-monitor segment is the last bit of the fourth byte of said command. But because the byte in which said last bit occurs contains no MOVE bit information, according to the  
5 rules of message composition of the preferred embodiment, one full signal word of padding bits follows said command.

When the message of Fig. 2 is transmitted, a given EOFS valve receives the transmission of said message from a particular transferring apparatus and transfers information  
10 to a particular receiving apparatus. Said valve is adapted and preprogrammed to process eight-bit bytes as signal words. The information at the EOFS Standard Word Location of said valve is the EOFS WORD of the preferred embodiment:

"11111111". The EOFS Standard Length Location and EOFS WORD  
15 Counter of said valve each hold one byte of binary information. The binary information at said EOFS Standard Length Location is "00001011", a binary number whose decimal equivalent is eleven. The binary information at said EOFS WORD Counter is "00000000", a binary number whose decimal  
20 value is zero.

Receiving the first byte of said message causes said valve to place information of said byte at said EOFS Word Evaluation Location and to compare the information at said Location, "10010100", to the EOFS WORD information at said  
25 EOFS Standard Word Location, "11111111". No match results which causes said valve automatically to set the information of said EOFS WORD Flag to "1". Automatically said valve determines the value of said information at said Flag is "1" which causes said valve to execute said transfer-all-word-  
30 information instructions. Automatically said valve compares the information at said EOFS WORD Counter, zero, to said zero information that is among the preprogrammed information of said valve. (The binary value of each instance of zero information is "00000000".) A match results which causes  
35 said valve automatically to set the information of said EOFS

77

Empty Flag to "0". Automatically said valve determines that the value of said information at said EOFs Empty Flag is "0" and skips executing said transfer-counted-information instructions. Automatically said valve continues executing  
5 conventional ones of said transfer-all-word-information instructions; transfers information of said first byte at said EOFs word evaluation location--which information is "10010100"--to said receiving apparatus; completes said word evaluation sequence, in respect to said first byte; and  
10 transfers handshake information to said transferring apparatus that informs said apparatus that said valve is ready to receive next signal word information.

Receiving said handshake information causes said transferring apparatus to transfer the next byte of said  
15 message to said valve.

Receiving said next byte, which is the second byte, causes said valve to place information of said byte at said EOFs Word Evaluation Location and to compare the information at said Location, "11001000", to the EOFs WORD information at  
20 said EOFs Standard Word Location, "11111111". No match results which causes said valve to set the information of said EOFs WORD Flag to "1". Automatically said valve determines that the information at said Flag is "1" which causes said valve to execute said transfer-all-word-  
25 information instructions. Automatically said valve compares the information at said EOFs WORD Counter, zero, to said zero information that is among the preprogrammed information of said valve. A match results which causes said valve to set the information of said EOFs Empty Flag to "0".  
30 Automatically said valve determines that the information at said EOFs Empty Flag is "0". Automatically said valve continues executing conventional transfer-all-word-information instructions; transfers information of said second byte at said EOFs word evaluation location--which  
35 information is "11001000"--to said receiving apparatus;

78

completes said word evaluation sequence, in respect to said second byte; and informs said transferring apparatus that said valve is ready to receive next signal word information which causes said apparatus to transfer to said valve the 5 next byte of said message.

Receiving said next byte, which is the third byte, causes said valve to place information of said byte at said EOFs Word Evaluation Location and to compare the information at said Location, "11111111", to the EOFs WORD at said EOFs 10 Standard Word Location, "11111111". A match results, causing said valve to set the information of said EOFs WORD Flag to "0". Automatically said valve determines that the information at said Flag is "0" which causes said valve to execute said process-EOFs-WORD instructions. Automatically, 15 in a fashion well known in the art, said valve increases the value of the information at said EOFs WORD Counter by an increment of one from "00000000" to "00000001". Automatically said valve compares the information at said EOFs WORD Counter, "00000001", to the information at said 20 EOFs Standard Length Location, "00001011". No match results which causes said valve automatically to set the information of said EOFs Complete Flag to "1". Automatically said valve determines that the value of said information at said EOFs Complete Flag is "1" which causes said valve 25 automatically to complete said word evaluation sequence, in respect to said third byte, without transferring any information of said byte to said receiving apparatus. Automatically said valve then informs said transferring apparatus that said valve is ready to receive next signal word information which causes said apparatus to transfer to 30 said valve the next byte of said message.

Receiving said next byte, which is the fourth byte, causes said valve to place information of said byte at said EOFs Word Evaluation Location, which information is 35 "11111111". In so placing said information at said Location,

79

said valve automatically overwrites and obliterates the information of the third byte that had been at said Location. Automatically said valve then compares the information at said Location, "11111111", to the EOFs WORD information at 5 said EOFs Standard Word Location, "11111111". A match results, causing said valve to set the information of said EOFs WORD Flag to "0". Automatically said valve determines that the information at said Flag is "0", which causes said valve to increase the value of the information at said EOFs 10 WORD Counter from "00000001" to "00000010", a binary number whose decimal equivalent is two. Automatically said valve compares said "00000010" to the information at said EOFs Standard Length Location, "00001011". No match results which causes said valve to set the information of said EOFs 15 Complete Flag to "1". Automatically said valve determines that the value of said information at said EOFs Complete Flag is "1" which causes said valve to complete said word evaluation sequence, in respect to said fourth byte, without transferring any information of said byte to said receiving 20 apparatus. Automatically said valve then informs said transferring apparatus that said valve is ready to receive next signal word information which causes said apparatus to transfer to said valve the next byte of said message.

Receiving said next byte, which is the fifth and last 25 byte, causes said valve to place information of said byte at said EOFs Word Evaluation Location, which information is "00000000". In so placing said information at said Location, said valve automatically overwrites and obliterates the information of the fourth byte at said Location. 30 Automatically said valve then compares the information at said Location, "00000000", to the EOFs WORD information at said EOFs Standard Word Location, "11111111". No match results which causes said valve to set the information of said EOFs WORD Flag to "1". Automatically said valve 35 determines that the information at said Flag is "1" which

80

causes said valve to execute said transfer-all-word-information instructions. Automatically said valve compares the information at said EOFS WORD Counter, "00000010", to said zero information, "00000000", that is among the 5 preprogrammed information of said valve. No match results which causes said valve to set the information of said EOFS Empty Flag to "1". Automatically said valve determines that the information at said EOFS Empty Flag is "1" which causes said valve to execute said transfer-counted-information 10 instructions. Said instructions cause said valve automatically to transfer one instance of said EOFS WORD information at said EOFS Standard Word Location, "11111111", to said receiving apparatus then decrease the value of the information at said EOFS WORD Counter by a decrement of one-- 15 that is, from "00000010" to "00000001"--then compare the information at said EOFS WORD Counter to said zero information, "00000000". Because no match occurs, said valve automatically transfers one more instance of said EOFS WORD information, "11111111", to said receiving apparatus 20 then decreases the value of the information at said EOFS WORD Counter by an additional decrement of one--that is, from "00000001" to "00000000"--then compares said information to said zero information, "00000000". A match occurs. In a fashion well known in the art, the fact of said match causes 25 said valve automatically to continue executing transfer-all-word-information instructions. Automatically said valve transfers information of said fifth byte at said EOFS word evaluation location--which information is "00000000"--to said receiving apparatus; completes said word evaluation sequence, 30 in respect to said fifth and last byte of the message of Fig. 2K; and informs said transferring apparatus that said valve is ready to receive next signal word information which causes said apparatus to transfer to said valve the next byte of said message as soon as said apparatus receives and is 35 prepared to transfer said byte.

21

The example of Fig. 2K illustrates how receiving each signal word causes an EOFs valve to evaluate the information content of said word; to transfer words that are not EOFs WORDS; to retain count information of words that are EOFs WORDS so long as said words occur in uninterrupted sequences of EOFs WORDS which sequences are shorter than the number of EOFs WORDS in an instance of end of file signal information; and when receiving any given signal word that is not an EOFs WORD interrupts such a sequence, to transfer information of each retained EOFs WORD before transferring information of said given signal word. The example of Fig. 2K does not illustrate the detecting of an end of file signal; however, an example of such detecting is provided below.

In this specification, MOVE bits are called "MOVE" bits because MOVE bit information in any given signal word causes each EOFs valve that processes the information of said word to "move"--that is, to transfer--information of said word to receiving apparatus external to said valve during the word evaluation sequence of said word rather than retaining said information.

Reasons should now be clear why padding bits are always MOVE bits and why, in a SPAM message, a full signal word of padding bits follows a signal word that is the last signal word in which command information occurs and that contains no MOVE bits. The command of Fig. 2K is such a command, and the fourth byte is such a word. In its automatic fashion for identifying end of file signals, no EOFs valve that receives said fourth byte transfers said byte until it receives a subsequent signal word that contains a MOVE bit. In the present invention there is no assurance that every EOFs valve immediately receives a next signal word as soon as it completes the word evaluation sequence, in respect to any given signal word. Thus to ensure that all apparatus to which messages are addressed process message information in the fastest possible fashion, all messages

82

that do not end with end of file signals do end with signal words that contain at least one MOVE bit.

One final rule of message composition remains. In order to define end of file signals precisely, a signal word  
5 that contains at least one MOVE bit is always transmitted immediately before the uninterrupted sequence of EOFs WORDs of any given end of file signal. Were a given signal word that contained no MOVE bits to be transmitted immediately before the uninterrupted sequence of a given end of file  
10 signal, said word would contain only EOFs bits and would be an EOFs WORD. Any EOFs valve processing said word and said signal would process said word as one of the EOFs WORDs of said uninterrupted sequence. Said valve would count said word erroneously as part of said sequence rather than as part  
15 of the information preceding said sequence and would count at least the last EOFs WORD of said sequence erroneously as part of the message following said signal rather than as part of said signal. In order to avoid such erroneous processing, any given instance of the uninterrupted sequence of EOFs  
20 WORDs of an end of file signal is preceded by signal word that is not an EOFs WORD.

This final rule may be satisfied in a number of different ways. For example, end of file signals could include the signal word preceding said uninterrupted  
25 sequence. Rather than being an uninterrupted sequence of eleven EOFs WORDs, an end of file signal could be twelve words long with the first word containing MOVE bit information. And subscriber station apparatus could be adapted and preprogrammed for detecting such signals.

30 As related above, in the preferred embodiment, end of file signals are composed just of the uninterrupted sequence of EOFs WORDs described above, and the signal words that precede said sequences are part of the last segment information preceding said signals. To prevent erroneous  
35 processing while satisfying the final rule of message

P3

composition, in any given pre-transmission evaluation of an instance of SPAM message information, if the EOFs valve of said evaluation retains information the last signal word of said information in the course of the word evaluation  
5 sequence of said word rather than transferring information of said word, the binary information of said instance is rewritten, in a fashion well known in the art that may be manual, before being embedded and transmitted. Said binary information is rewritten to end with a final signal word that  
10 contains MOVE bit information and still cause substantively the same information processing at subscriber stations.

In this fashion, the signal information of any given end of file signal is distinctive, and EOFs detectors detect end of file signals precisely.

15 Despite the fact that the use of end of file signals involves time consuming processing, the preferred embodiment's system for distinguishing individual messages from one another in message streams has significant advantages over alternate techniques.

20 By comparison with systems that process fixed length and/or fixed format messages, the use of end of file signals permits great flexibility. Messages can be of any length and can contain any information that digital receiver station apparatus can process.

25 By comparison with systems that distinguish messages from one another by means of distinctive signals that separate the end of each message from the beginning of the next, end of file signals are used in the preferred embodiment only with some messages. Many messages, such as  
30 the second and third messages of the message stream of Fig. 2I, do not require end of file signals. Furthermore, as will become more apparent in the course of this specification, messages that consist of commands alone often have higher priority for processing speed than do the messages that  
35 contain last segment information. Since only messages that

84

contain last segment information require end of file signals, end of file signals are often transmitted and processed at times when speed of processing is of relative unimportance.

Finally, because long cadence signals are processed at  
5 ends of messages rather than at beginnings, the preferred embodiment reduces the relative importance of the processing speed associated with such signals even further. In the preferred embodiment, subscriber station apparatus have capacity for commencing to process received command and  
10 information segment information before receiving the end of file signal associated with said information. The commencement of processing of the command and information segment information of any given message need never be delayed until after an end of file signal, associated with  
15 said message, is detected.

The preferred embodiment has the advantage of requiring that long cadence signals that require time consuming processing be transmitted only with some messages and then only at times when processing speed is of relatively  
20 low priority. In so doing, the preferred embodiment makes it possible to transmit in the shortest, simplest formats messages that have high priority for processing speed and to process said messages the fastest fashion.

#### 25 THE NORMAL TRANSMISSION LOCATION

SPAM signals are generated at original transmission stations or intermediate transmission stations and embedded in television or radio or other programming transmissions by conventional generating and embedding means, well known in  
30 the art. Said signals may be embedded in transmissions at said stations immediately prior to transmitting said transmissions via conventional broadcast or cablecast means, well known in the art. Alternatively, said signals may be embedded in transmissions that are then recorded, in a  
35 fashion well known in the art, on an appropriate conventional

85

video, audio or other record media. Playing back said media on appropriate player apparatus will cause said apparatus to retransmit said transmissions with said SPAM signals embedded precisely as they were embedded when said transmissions were  
5 recorded.

SPAM signals can be embedded in many different locations in electronic transmissions. In television, SPAM signals can be embedded in the video portion or in the audio portion of the transmission. In the video portion, SPAM  
10 signals can be embedded in each frame on one line such as line 20 of the vertical interval, or on a portion of one line, or on more than one line, and they will probably lie outside the range of the television picture displayed on a normally tuned television set. SPAM signals can be embedded  
15 in radio audio transmissions. In the audio of television and radio transmissions, SPAM signals will probably be embedded in a portion of the audio range that is not normally rendered in a form audible to the human ear. In television audio, they are likely to lie between eight and fifteen kilohertz.  
20 In broadcast print and data communications transmissions, SPAM signals can accompany conventional print or data programming in the conventional transmission stream.

In television, the normal transmission location of the preferred embodiment is in the vertical interval of each  
25 frame of the television video transmission. Said location begins at the first detectable part of line 20 of the vertical interval and continues to the last detectable part of the last line of the vertical interval that is not visible on a normally tuned television set.

30 In radio, the preferred normal transmission location is in the audio above the range of the radio transmission that is normally audible to the human ear.

In broadcast print or data communications, the preferred normal transmission location for SPAM signals is in  
35 the same location as the conventional information. More

86

precisely, conventional print of data information is transmitted in SPAM transmissions. Any given instance of conventional print or data information is transmitted in a SPAM information segment that is preceded by a "01" header 5 SPAM command or a "11" header, which command or header addresses conventional print or data processing apparatus at subscriber stations and causes said apparatus to process said conventional information in the conventional fashion. In said transmissions, other SPAM commands and information 10 address and control subscriber station apparatus in other SPAM functioning.

(Hereinafter, the preferred normal location for transmitting signals in any given communication medium is called, the "normal transmission location".)

15 In the preferred embodiment, while receiver station decoder apparatus may be controlled, in fashions described below, to detect information segment information outside the normal transmission locations, SPAM commands and cadence information are always transmitted in normal transmission 20 locations. In the present invention, the object of many decoders is to detect only command information such as meter-monitor segment information. Having one unchanging location for the transmission of command information in any given television, radio, broadcast print, or data transmission 25 permits decoder apparatus to search just one unchanging portion of said transmission to detect commands. Having the same fixed location for cadence information enables said decoder apparatus to distinguish all command information in said transmission.

30

#### OPERATING SIGNAL PROCESSOR SYSTEMS ... INTRODUCTION

Five examples illustrate methods of operating signal processing system apparatus. Each focuses on subscriber stations where the signal processor system of Fig. 2D and the 35 combined medium apparatus of Fig. 1 share apparatus and

operate in common.

Fig. 3 shows one such subscriber station. In Fig. 3, the decoder, 203, of Fig. 1 is also an external decoder of the signal processor system of signal processor, 200. Like 5 decoders, 27, 28, and 29, in Fig. 2D, decoder, 203, has capacity for transferring SPAM information to buffer/comparator, 8, of signal processor, 200, and to buffer/comparator, 14. In addition, signal processor, 200, has capacity for transferring SPAM signals from a particular 10 jack port of controller, 12, to microcomputer, 205.

Fig. 3 also shows SPAM-controller, 205C, to which signals that are addressed to URS microcomputers, 205, are transferred from decoder, 203, and from signal processor, 200. SPAM-controller, 205C, is a control unit like 15 controller, 39, of decoder, 203, with buffer capacity for receiving multiple inputs; RAM and ROM for holding operating instructions and other information; EOFs valve capacity for detecting end of file signals and regulating the flow of SPAM signals; microprocessor capacity for processing; capacity for 20 transferring information to and receiving information from the central processor unit (hereinafter, "CPU") of microcomputer, 205; and capacity for transferring information to one or more input buffers of microcomputer, 205. SPAM-controller, 205C, operates independently of said CPU although 25 said CPU has capacity to interrupt SPAM-controller, 205C, in an interrupt fashion well known in the art. SPAM-controller, 205C, also has capacity to control directly to the aforementioned PC-MicroKey 1300 System without affecting the operation of said CPU.

30 All five examples describe signal processing variations that relate to the Fig. 1C combining of "One Combined Medium."

The first focuses on the basic operation, in "One Combined Medium," of decoder, 203; SPAM-controller, 205C; and 35 microcomputer, 205. No signals require decryption. No meter

??

information is collected. No monitor information is processed. Combined information is displayed at each subscriber station.

In the second example, the combining of Fig. 1C occurs only at selected subscriber stations. The second combining synch command is partially encrypted, and said stations are preprogrammed with particular information that is necessary to decrypt said command. At said stations, said command causes its own decryption and the combining of Fig. 1C. In addition, said command causes signal processor apparatus at said stations to retain meter information that a remote billing agency can use as a basis for charging the subscribers of said stations for displaying the combined information of said combining. At all other stations, no information is decrypted, no combining occurs, and no meter information is collected.

In the third example, combined information is displayed at each subscriber station just as in the first example. In addition, monitor information is processed at selected stations for one or more so-called "ratings" agencies (such as the A. C. Nielsen Company) that collect statistics on viewership and programming usage.

The fourth example provides a second illustration of restricting the combining of Fig. 1C to selected subscriber stations through the use of encryption/decryption techniques and metering. In addition, the fourth example shows how monitor information is collected at selected ones of said selected stations.

The fifth example adds program unit identification signals identified at decoders, 30 and 40, of signal processor, 200.

In the last three examples, the first combining synch command causes selected subscriber stations to transfer recorded meter information and monitor information to one or more remote computer stations of said billing agencies and

89

ratings agencies and causes computers at said remote agencies to receive and process said transferred information.

Each example focuses on the processing of the three signal messages of the Fig. 1C combining. The information of 5 said messages include three combining synch commands and one program instruction set.

The first message is of the information associated with the first combining synch command. Said first command has a "01" header, an execution segment, and a meter-monitor 10 segment of six fields. Said command is followed by an information segment that contains said program instruction set, and said information segment is followed by an end of file signal. Said first command addresses URS microcomputers, 205, and causes said computers, 205, to load 15 and run the program instruction set transmitted in the information segment. Each meter-monitor segment field of said command contains information that identifies one of the following:

20

- . the origin of said "Wall Street Week" transmission,
- . the subject matter of said "Wall Street Week" program,

25

- . the program unit of said program,
- . the day of said transmission within a particular one hundred year period,

30

- . the supplier of the program instruction set in the information segment following said first combining synch command, and

- . the format of said meter-monitor segment information.

35

90

(Hereinafter, meter-monitor information that identifies the program unit of a given program may also be called the "program unit identification code".)

The second message is of the information associated with the second combining synch command. Said second command has a "00" header, an execution segment, and a meter-monitor segment of five fields and addresses URS microcomputers, 205. Said second command causes said computers, 205, to combine the Fig. 1A information of each microcomputer, 205, with the information of Fig. 1B and transmit the combined information to monitors, 202M. Each meter-monitor segment field of the second command contains information of one of the following:

- 15 . the subject matter of said "Wall Street Week" program,
- . the program unit of said program,
- . the unique code of said overlay given said program unit information,
- 20 . the minute of said transmission within a particular one month period, and
- 25 . the format of said meter-monitor segment information.

The third message is of the information associated with the third combining synch command. Said third command has only a "10" header and an execution segment and addresses URS microcomputers, 205. Said command causes said computers, 205, to cease combining and transmit only the received composite video transmission to monitors, 202M, and to continue processing in a predetermined fashion (which fashion may be determined by the aforementioned program instruction

91

set).

In those examples that focus on encrypted commands, the meter-monitor segments of each encrypted command includes an additional meter-monitor field:

5

. meter instructions.

10 In said examples, the meter-monitor format field information of said commands reflects the presence of said additional field.

As described above, said signals are of binary information with error correcting bit information and are  
15 embedded, transmitted, and received in the normal transmission pattern of the "Wall Street Week" television transmission.

All subscriber station apparatus are fully preprogrammed to perform automatically each step of each  
20 example. No manual step is required at any station.

In each example, the apparatus of Fig. 3 are preprogrammed to detect embedded signal information, to transfer said information to addressed apparatus, and to operate under control of said information. Apparatus of  
25 decoder, 203, are preprogrammed to detect signal information embedded in the normal transmission pattern and to correct, convert, and transfer said information to its addressed apparatus. Apparatus of signal processor, 200, are preprogrammed to decrypt information upon instruction and to  
30 transfer information to its addressed apparatus. For one or more remote services that meter and charge subscribers for the use of information or that audit such remote metering services, apparatus of signal processor, 200, are preprogrammed to select, process, and record meter  
35 information and to transfer recorded meter information to one

92

or more remote station computers.

In each example, the EOFs valves located at controller, 39, of decoder, 203; at buffer/comparator, 8, of signal processor, 200; and at SPAM-controller, 205C, are 5 preprogrammed to detect end of file signals that consist of eleven sequentially transmitted EOFs WORDs. Thus the binary information of eleven--"00001011"--is at the EOFs Standard Length Location of each of said EOFs valves.

In the third, fourth, and fifth examples, appropriate 10 apparatus of Fig. 3 are also preprogrammed to assemble, record, and transmit to one or more remote locations monitor information for one or more services that sample selected subscriber stations (said stations being preprogrammed for this purpose) to collect statistical data on programming and 15 information usage and/or to audit selectively the customer accounting of remote meter services.

In each example, receiving SPAM signal information at each apparatus of Fig. 3 causes subscriber station apparatus automatically to process said information in the 20 preprogrammed fashions of said apparatus.

At the outset of each example, particular meter record information of prior programming exists at a particular location at buffer/comparator, 14, of signal processor, 200. Said record information documents the fact that before 25 receiving the "Wall Street Week" program, tuner, 215, transmitted to monitor, 202M, particular programming that contained embedded SPAM commands and information with particular meter instructions. Information of said commands and information caused buffer/comparator, 14, to 30 retain said meter record information. In the third and subsequent examples, monitor record information of said prior programming also exists at a particular location at said buffer/comparator, 14, associated with the source mark of decoder, 203.

35 In each example, the recorder, 16, of signal

95

processor, 200, has reached a level of fullness where the recording of the next signal record received from the buffer/comparator, 14, of signal processor, 200, will cause the quantity of signal records recorded at recorder, 16, to  
5 equal or exceed the particular fullness information of said recorder, 16. Whenever said quantity equals or exceeds said fullness information, recorder, 16, is preprogrammed to commences a particular telephone signal record transfer sequence that is fully automatic for which recorder, 16;  
10 controller, 20; auto dialer, 24; and telephone connection, 22, are each preprogrammed. Under control of the preprogrammed instructions of said sequence, signal processor, 200, telephones one or more remote billing station computers and/or one or more remote monitor information  
15 collection station computers and transfers selected record information to said computers.

In each example, all receiver station apparatus is on and fully operational.

## 20 OPERATING SIGNAL PROCESSOR SYSTEMS ... EXAMPLE #1

The first example elaborates on the Fig. 1C combining described above in "One Combined Medium" and focuses on the operation of decoder, 203, SPAM-controller, 205C, and microcomputer, 205, on the execution of controlled functions,  
25 and on the the use of cadence information to organize signal processing. The example begins as divider, 4, starts to transfer to decoder, 203, in its outputted composite video transmission, the embedded binary information of the first message. At the outset of example #1, controller, 39, of  
30 decoder, 203, and SPAM-controller, 205C, have each identified an end of file signal and await header information.

Receiving said embedded binary information at decoder, 203, (which does not include a filter, 31, or a demodulator, 32, because its input is a composite video transmission)  
35 causes line receiver, 33, automatically to detect and

94

transfer said embedded information to digital detector, 34, which automatically detects the binary information with correcting information in said embedded information and transfers said binary information with correcting information 5 to controller, 39. Using forward error correction techniques, well known in the art, and employing particular correcting information, controller, 39, automatically checks said information, as it is received, and corrects it as necessary then discards said particular correcting 10 information retaining only the corrected information. Using conversion protocol techniques, well known in the art, controller, 39, then automatically converts said corrected information into binary information that receiver station apparatus can receive and process. In this fashion, the 15 binary information of the first message--more precisely, the first combining synch command and its associated program instruction set and end of file signal--are received and converted at decoder, 203.

Once the information of any given point-to-multipoint 20 SPAM transmission has been checked, corrected, and converted in the foregoing fashion, subscriber station apparatus communicate said information point-to-point using flow control and error correction techniques, well known in the art, that include handshaking and requesting retransmission. 25 Thereafter, any given transmission of SPAM information, so corrected and converted, contains not only bits of communicated SPAM information but also so-called "parity bits" that convey error correcting information. At present, the conventional practice is for every ninth bit to be a 30 parity bit that is used, in a fashion well known in the art, to check the correctness of the preceding eight bits, or "byte," of communicated data.

Frequently in this disclosure, specific quantities of bits and bit locations are cited. Said bits are often 35 specified as being "sequential" and "in their order after

95

conversion," and said bit locations are often "contiguous."  
Unless otherwise stated, said quantities refer only to bits  
of communicated SPAM information and bit locations that hold  
communicated SPAM information. No attempt is made to account  
5 for the presence of parity bits among transmitted bits of  
SPAM information or at particular memory locations because  
techniques for distinguishing bits of communicated data from  
parity bits and for processing bits of communicated  
information separately from parity bits are well known in the  
10 art.

Automatically, after said binary information is  
converted, said information is inputted to the EOFs valve of  
controller, 39, which processes said information in the  
fashion described above, comparing each signal word of said  
15 information to EOFs WORD information and transferring said  
binary information, signal word by signal word, until an end  
of file signal is detected.

Receiving the header and execution segment of said  
first message causes controller, 39, to determine that said  
20 message is addressed to URS microcomputers, 205, and to  
transfer said message to microcomputer, 205. So transferring  
said message is the controlled function that the information  
said header and execution segment cause controller, 39, to  
perform. Automatically, as said EOFs valve transfers  
25 converted binary information of said first message,  
controller, 39, selects and records at particular SPAM-header  
register memory a particular preprogrammed constant number of  
the first converted bits of said binary information. Said  
constant number is the number of bits in a SPAM command  
30 header. (Hereinafter, said constant number is called "H".)  
From the first bit of said binary information, H bits are  
selected and recorded, in their order after conversion, at  
said SPAM-header memory. Then, automatically, controller,  
39, determines that said information at SPAM-header memory  
35 (which is the "01" header of the first combining synch

96

command and designates a SPAM command that is followed by an information segment) does not match particular 11-header-invoking information that is "11". (In other words, the header of said message does not designate a SPAM message that consists of a header followed immediately by an information segment.) Not resulting in a match causes controller, 39, automatically to select a second preprogrammed constant number of next bits and record said bits, in their order after conversion, at particular SPAM-exec register memory.

10 Said second constant number is the particular number of bits in a SPAM execution segment. (Hereinafter, said second constant number is called "X".) Beginning with the next bit of said binary information immediately after said H bits, controller, 39, selects X bits and records said bits, in

15 their order after conversion, at said SPAM-exec memory. Then, automatically, by comparing the information at said SPAM-exec memory (which information is the execution segment of the first combining synch command) with preprogrammed controlled-function-invoking information, controller, 39,

20 determines that said information at memory matches particular this-message-addressed-to-205 information that causes controller, 39, to execute particular preprogrammed transfer-to-205 instructions. Said instructions cause controller, 39, to transfer to SPAM-controller, 205C, the SPAM message

25 associated with the particular information at SPAM-header memory. Automatically, said instructions cause controller, 39, to activate the output port that outputs to SPAM-controller, 205C, then compare said information at SPAM-header memory to preprogrammed header-identification

30 information. Automatically, controller, 39, determines that said information matches particular "01" information. Said match causes controller, 39, automatically to execute particular transfer-a-01-or-an-11-header-message instructions.

35 A "01" header distinguishes a message that contains

97

lowest priority information. Any given instance of a message with a "01" header ends with an end of file signal. Accordingly, said instructions cause controller, 39, to transfer, from the start of said message, all information 5 received from said valve until said valve detects and transfers the information of an end of file signal. Automatically controller, 39, commences transferring said binary information, starting with said first H bits and transferring said information in its order after conversion, 10 signal word by signal word, as said binary information is outputted by said EOFs valve. In due course, the EOFs valve of controller, 39, receives the last signal word of the information segment of said first message. To satisfy the final rule of message composition cited above, said word, 15 being an instance of a final signal word preceding an end of file signal, contains MOVE bit information and is not an EOFs WORD. Said valve transfers said word which causes controller, 39, to transfer said word to SPAM-controller, 205C. (When said valve receives information of the next 20 signal word after said word, the information of the EOFs WORD Counter of said valve is "00000000" because said word contained MOVE bit information.)

Immediately after embedding and transmitting said last word, the aforementioned program originating studio that is 25 the original transmission station of the programming of "One Combined Medium" generates and embeds an end of file signal in said programming and transmits said signal. More precisely, said studio generates, embeds, and transmits eleven consecutive EOFs WORDs of binary information.

30 Receiving said first EOFs WORD causes said valve to place information of said WORD at the EOFs Word Evaluation Location of said valve and to compare the information at said Location to the EOFs WORD at the EOFs Standard Word Location of said valve. A match results, causing said valve, in the 35 fashion described above, to increase the value of the

98

information at said EOFs WORD Counter by an increment of one from "00000000" to "00000001". Automatically said valve determines, in the fashion described above, that the "00000001" at said EOFs WORD Counter does not match the 5 "00001011" at said EOFs Standard Length Location which causes said valve to cause the apparatus that inputs signal words to said valve to transfer to said valve the next signal word of said message.

In this fashion, said valve processes sequentially the 10 inputted information of each of the next ten EOFs WORDs, each time increasing the value of the information at said EOFs WORD Counter by an increment of one. When, in the course of the word evaluation sequence of the eleventh and last EOFs WORD, said valve so increases said value, the information at 15 said Counter is "00001011". Automatically said valve determines that said "00001011" matches the "00001011" at said EOFs Standard Length Location which causes said valve to execute the complete-signal-detected instructions described above in "Detecting End of File Signals." Said instructions 20 cause said valve to initiate the transmission of the aforementioned EOFs-signal-detected information to the CPU of controller, 39, as an interrupt signal then to wait for a control instruction from controller, 39, before processing inputted information further.

25 Receiving said EOFs-signal-detected information at said CPU causes controller, 39, to determine, in a predetermined fashion, that said end of file signal is part of a SPAM message being transferred under control of instructions invoked by transfer-to-addressed-apparatus 30 information. Said determining causes controller, 39, automatically to transmit the aforementioned transmit-and-wait instruction to said valve which causes said valve to transfer one complete end of file signal (which signal is automatically transferred by controller, 39, to SPAM- 35 controller, 205C). Automatically, said valve outputs,

99

sequentially, the binary information of eleven instances of an EOFs WORD; then sets the information at said EOFs WORD Counter to "00000000"; initiates transmission of the aforementioned complete-and-waiting information to the CPU of controller, 39, as an interrupt signal; and commences waiting for a control instruction from controller, 39, before processing next inputted information. In so doing, controller, 39, transfers an end of file signal as a part of said first message and ensures that apparatus to which said message is transferred receive all cadence information necessary to process said message.

Having transferred the binary information of said first message, controller, 39, prepares all apparatus of decoder, 203, as required, to receive the next instance of SPAM message information. Automatically, controller, 39, deactivates all output ports; compares the information at said SPAM-header register memory to particular preprogrammed cause-retention-of-exec information that is "01" and determines a match which causes controller, 39, to transfer information of said information at SPAM-exec register memory to particular SPAM-last-01-header-exec register memory (thereby placing information of the execution segment of the first combining synch command at said SPAM-last-01-header-exec memory); then causes all apparatus of decoder, 203, to delete from memory all information of said binary information except information at said SPAM-last-01-header-exec memory. Then, after receiving said complete-and-waiting information, controller, 39, transmits particular reopen-flow instructions that cause said EOFs valve to recommence processing and transferring inputted signal words in its preprogrammed fashion, and controller, 39, commences waiting to receive from said valve the binary information of a subsequent SPAM header.

(If said information at SPAM-exec memory had failed to match any controlled-function-invoking information at the

100

aforementioned comparing, said failure to match would have signified that the subscriber station of Fig. 3 did not have capacity to execute the controlled function of said command. Whenever comparing execution segment information of any given  
5 command to preprogrammed controlled-function-invoking information at any given subscriber station SPAM apparatus results in a failure to match, said failure to match causes said apparatus to discard all received information of the message of said execution segment. In the case of a "01"  
10 header message such as said first message, said apparatus discards all received information, except information at register memory, until the EOFs valve of said apparatus, operating in the aforementioned fashion, transfers said EOFs-signal-detected information to the CPU of said apparatus.  
15 Said apparatus discards said information, in a fashion described more fully below, by placing each successively received signal word at a particular memory location, and in so doing, overwriting and obliterating the information of the prior signal word. Then receiving said EOFs-signal-  
20 detected information causes said apparatus to transmit the aforementioned discard-and-wait instruction to said valve causing said valve, in its preprogrammed discard-and-wait fashion, to discard all information of the end of file signal of said message, set the information of the EOFs WORD Counter  
25 of said valve to "00000000", then transmit said complete-and-waiting information to said apparatus. Said complete-and-waiting information causes said apparatus to perform all functions performed by controller, 39, in the foregoing paragraph.)

30 At SPAM-controller, 205C, of the subscriber station of Fig. 3 (and at SPAM-controllers, 205C, of URS microcomputers, 205, at other subscriber stations), receiving said transferred binary information of the first message causes all apparatus automatically to process the information of  
35 said message in the preprogrammed fashions of said apparatus.

/01/

Automatically the EOFs valve of SPAM-controller, 205C, commences processing and transferring said information until an end of file signal is detected.

Receiving the header and execution segment of said  
5 first message causes SPAM-controller, 205C, to determine the controlled function or functions that said message instructs URS microcomputers, 205, to perform and to execute the instructions of said functions. Automatically, as said valve transfers information, SPAM-controller, 205C, selects the  
10 first H converted bits of said information and records said bits at particular SPAM-header-@205 register memory, then determines that said information at SPAM-header-@205 memory (which is the "01" header of the first message) does not match particular 11-header-invoking-@205 information that is  
15 "11". Not resulting in a match causes controller, 39, automatically to select the next X bits of said transferred binary information and record said bits at particular SPAM-exec-@205 register memory. Automatically SPAM-controller, 205C, compares the information at said SPAM-exec-@205 memory  
20 (which information is the execution segment of the first combining synch command) with preprogrammed controlled-function-invoking-@205 information. Said comparing results in a match with particular execute-at-205 information that causes SPAM-controller, 205C, to invoke particular  
25 preprogrammed load-run-and-code instructions that control the loading of particular binary information at the main RAM of microcomputer, 205; the running of the information so loaded; and the placing of particular identification code information at particular SPAM-controller memory. Said binary  
30 information that is loaded and run is the information that begins at the first bit of the information segment that follows said X bits, continues through the last bit of said segment, and is, in the "One Combined Medium" application, the information of said program instruction set.  
35 Automatically, SPAM-controller, 205C, executes said load-run-

/02

and-code instructions.

(No change takes place between controller, 39, and SPAM-controller, 205C, in the information of the execution segment of the first combining synch command. Thus the  
5 binary image of the particular controlled-function-invoking information that said information matches at controller, 39-- more precisely, the aforementioned particular this-message-addressed-to-205 information--is identical to the binary  
10 image of the particular controlled-function-invoking-@205 information that said information matches at SPAM-controller, 205C--said particular execute-at-205 information. While said this-message-addressed-to-205 information and said execute-at-205 information are identical in image, they bear  
15 different names in this specification because they invoke different controlled functions. This is but one of many instances in this specification where a given SPAM command invokes different controlled functions at different apparatus because the apparatus are preprogrammed differently.)

To load and run said information, SPAM-controller, 20  
20 205C, must locate the position, in said transferred binary information, of said first bit and said last bit. Under control of said load-run-and-code instructions, SPAM-controller, 205C, compares the information at said SPAM-header-@205 memory with particular preprogrammed header-  
25 identification-@205 information and determines that said information at memory matches particular "01" information. In other words, to locate said first bit, SPAM-controller, 205C, must process the command information of an "01" header message including the length token of a meter-monitor  
30 segment.

Under control of said load-run-and-code instructions, said match causes SPAM-controller, 205C, automatically to execute particular preprogrammed process-length-token-@205  
instructions. Automatically, said instructions cause SPAM-  
35 controller, 205C, to select a third preprogrammed constant

103

number of next bits and record said bits at particular memory. Said third constant number is the particular number of bits in an instance of SPAM meter-monitor format field length token information. (Hereinafter, said third constant number is called "L".) Beginning with the bit of said transferred binary information immediately after the last of said X bits, SPAM-controller, 205C, selects L bits and records said bits, in their order after conversion, at particular SPAM-length-info-@205 register memory.

10 Automatically SPAM-controller, 205C, compares the information at said SPAM-length-info-@205 memory with preprogrammed token-comparison-@205 information and determines that said information at memory matches particular token-comparison-@205 information (which particular information is called,

15 hereinafter, "W-token information"). Said match causes SPAM-controller, 205C, to place particular preprogrammed bit-length-number information at said SPAM-length-info-@205 memory. (Said particular bit-length-number information is called, hereinafter, "w-bits information".) Said information

20 is the precise number of bits, following the last of said L bits, that remain in the meter-monitor segment of the command associated with said length token. Said number is not a preprogrammed constant value such as H, X, and L that is the same for every SPAM command with a meter-monitor segment.

25 Rather, said number is a variable that may differ from one SPAM meter-monitor segment to the next. More precisely, it is, for any given meter-monitor segment, a selected one of several preprogrammed bit-length-number information alternatives. (Hereinafter, the number of the particular

30 selected bit-length-number alternative associated with any given length token is called "MMS-L" to signify that said number is L bits less than the number bits in the meter-monitor segment in which said length token occurs.)

Having executed said process-length-token-@205 instructions and continuing under control of said load-run-

35

104

and-code instructions, automatically SPAM-controller, 205C, adds L to the information (of MMS-L) at said SPAM-length-info-@205 memory and, in so doing, determines the exact number of bits in the meter-monitor segment of said command 5 (which is also the exact number of bits from the first bit after the last of said X bits to the last bit of said command). (Hereinafter, the exact number of bits in any given meter-monitor segment is called, "MMS".) Then SPAM-controller, 205C, causes information of the first MMS bits of 10 said transferred binary information that begin immediately after the last of said X bits to be stored at particular MMS-memory of SPAM-controller, 205C. In so doing, SPAM-controller, 205C, retains information of the meter-monitor segment of said first message. Then, automatically, SPAM- 15 controller, 205C, executes particular preprogrammed instructions, including assess-padding-bit-@205 instructions, that are described more fully elsewhere in this specification and that cause said SPAM-controller, 205C, to identify the particular signal word, associated with the command 20 information of said first message, that is the last signal word before the first signal word of the information segment of said message.

Then SPAM-controller, 205C, commences loading information at the main RAM of microcomputer, 205. 25 Automatically, under control of said load-run-and-code instructions, SPAM-controller, 205C, instructs microcomputer, 205, to commence receiving information from SPAM-controller, 205C, and loading said information at particular main RAM, in a fashion well known in the art. Automatically SPAM- 30 controller, 205C, commences transferring information to microcomputer, 205, beginning with said selected signal word. Automatically, as microcomputer, 205, receives said information, microcomputer, 205, loads said information at particular main RAM.

35 In due course, the EOFs valve of SPAM-controller,

105

205C, receives the aforementioned last signal word of the information segment of said first message, which is the last signal word of said program instruction set, and transfers said word which causes SPAM-controller, 205C, to transfer 5 said word to microcomputer, 205, and microcomputer, 205, to load said word at said RAM. (After transferring said word, the information of the EOFs WORD Counter of said valve is "00000000".)

Then said valve commences receiving information of the 10 eleven EOFs WORDs sequentially outputted by the EOFs valve of controller, 39, which information constitutes the end of file signal in said transferred binary information. Receiving the first EOFs WORD of said eleven causes the EOFs valve of SPAM-controller, 205C, to commence retaining information of said 15 WORD in the fashion described above. Said retaining causes SPAM-controller, 205C, to stop transferring information to microcomputer, 205, and microcomputer, 205, to stop loading information at said RAM. As said valve receives all said EOFs WORD information, said valve detects said end of file 20 signal just as the EOFs valve of controller, 39, detected the end of file signal in the binary information inputted to said valve. When, in the course of the word evaluation sequence of the eleventh and last EOFs WORD in said information, the EOFs valve of SPAM-controller, 205C, determines that the 25 information at the EOFs WORD Counter of said valve matches the information at the EOFs Standard Length Location of said valve, said valve initiates the transmission of the aforementioned EOFs-signal-detected information to the CPU of SPAM-controller, 205C, as an interrupt signal and commences 30 waiting for a control instruction from said CPU.

Receiving said EOFs-signal-detected information at said CPU while under control of said load-run-and-code instructions causes SPAM-controller, 205C, to cease loading and execute the remainder of said load-run-and-code 35 instructions. Automatically SPAM-controller, 205C, causes

106

microcomputer, 205, to cease loading information at said RAM and execute the information so loaded as so-called "machine executable code" of one so-called "job." Because information of said end of file signal is no longer needed, said  
5 instructions cause SPAM-controller, 205C, to transmit the aforementioned discard-and-wait instruction to said valve. Said instruction causes said valve to set the information at said EOFSS WORD Counter to "00000000" without transferring any information of said detected end of file signal; to initiate  
10 transmission of the aforementioned complete-and-waiting information to the CPU of SPAM-controller, 205C, as an interrupt signal; and to wait for a control instruction from SPAM-controller, 205C, before processing next inputted information.

15 Then SPAM-controller, 205C, commences executing the code portion of said load-run-and-code instructions. The instructions of said portion cause SPAM-controller, 205C, to compare the information at said SPAM-header memory to particular load-run-and-code-header information that is "01".  
20 A match results (which indicates that said first message contains meter-monitor information). Said match causes SPAM-controller, 205C, to execute particular preprogrammed evaluate-meter-monitor-format instructions and locate-program-unit instructions. Under control of said  
25 instructions and in a fashion that is described more fully below, SPAM-controller, 205C, locates the "program unit identification code" information in the information of the meter-monitor segment stored at said MMS-memory. Then said code-portion instructions cause SPAM-controller, 205C, to  
30 place said code information at particular SPAM-first-precondition register memory. In so doing, SPAM-controller completes said load-run-and-code instructions and completes the controlled functions executed by the execution segment information of said first message.

35 Having completed said controlled functions,

107

automatically SPAM-controller, 205C, prepares to receive the next instance of SPAM message information. Automatically, SPAM-controller, 205C, compares the information at said SPAM-header-@205 register memory to particular preprogrammed

5 cause-retention-of-exec-@205 information that is "01" and determines a match which causes SPAM-controller, 205C, to transfer information of said information at SPAM-exec-@205 register memory to particular SPAM-last-01-header-exec-@205 register memory. Then SPAM-controller, 205C, causes all

10 apparatus of SPAM-controller, 205C, to delete from memory all information of said transferred binary information except information at said SPAM-first-precondition and SPAM-last-01-header-exec-@205 memories. Finally, after receiving said complete-and-waiting information, SPAM-controller, 205C,

15 transmits particular instructions that cause said EOFs valve to commence processing and transferring inputted signal words, in its preprogrammed detecting fashion, and SPAM-controller, 205C, commences waiting to receive from said valve the binary information of a subsequent SPAM header.

20 As described in "One Combined Medium" above, loading and running said program instruction set causes microcomputer, 205, (and URS microcomputers, 205, at other subscriber stations) to place appropriate Fig. 1A image information at particular video RAM. In addition, running

25 said set also causes microcomputer, 205, after completing placing said image information at said RAM, to transfer particular number-of-overlay-completed information and instructions to SPAM-controller, 205C. Said information and instructions cause SPAM-controller, 205C, to place the number

30 "00000001" at particular SPAM-second-precondition register memory at SPAM-controller, 205C, signifying that said image information represents the first overlay of its associated video program.

(Had said information at SPAM-exec-@205 memory failed

35 to match any execute-at-205 information at the aforementioned

108

comparing, SPAM-controller, 205C, would have discarded discard all received information of the message of said information at SPAM-exec-@205 in the fashion described above.)

5

OPERATING S. P. SYSTEMS ... EXAMPLE #1 (SECOND MESSAGE)

Subsequently, the embedded information of the second message, which conveys the second combining synch command, is transferred from divider, 4, to decoder, 203.

10 In the same fashion that applied to the first message, receiving said embedded information causes the apparatus of decoder, 203, to detect, check, correct as necessary, and convert said information, into binary information of said second message. Automatically the EOF5 valve of controller,  
15 39, processes and transfers said information, signal word by signal word.

As with the first message, receiving the header and execution segment of said second message causes controller, 39, to determine that said message is addressed to URS  
20 microcomputers, 205, and to transfer said second message accordingly. Automatically, as said valve transfers said binary information, controller, 39, selects the first H converted bits and records said bits, in their order after conversion, at said SPAM-header register memory.  
25 Automatically controller, 39, determines that the information at said memory (which is the "00" header of the second combining synch command and signifies a SPAM command with a meter-monitor segment but no information segment) does not match said 11-header-invoking information that is "11". Not  
30 resulting in a match causes controller, 39, automatically to select the next X bits of said binary information immediately after said H bits, the execution segment of the second combining synch command, and record said X bits, in their order after conversion, at said SPAM-exec register memory.  
35 Then, automatically, by comparing the information at said

109

SPAM-exec memory with said controlled-function-invoking information, controller, 39, determines that said information at memory matches particular preprogrammed this-message-addressed-to-205 information that invokes said transfer-to-  
5 205 instructions. Automatically, controller, 39, executes said instructions; activates the output port that outputs to SPAM-controller, 205C; compares said information at SPAM-header memory to header-identification information; and determines that said information matches particular "00"  
10 information. (In other words, the header of said second message is "00".) Said match causes controller, 39, automatically to invoke particular preprogrammed transfer-a-00-header-message instructions.

A "00" header distinguishes a message that contains  
15 intermediate priority information but no lowest priority information. To identify the length and last bit of a "00" header message, controller, 39, must process length token information and may need to execute the aforementioned assess-padding-bit instructions to determine whether a full  
20 signal word of padding follows the last signal word in which command information occurs.

Automatically, said transfer-a-00-header-message instructions cause controller, 39, to execute particular preprogrammed process-length-token instructions. Said  
25 instructions cause controller, 39, to select the first L bits of said binary information immediately after the last of said X bits and record said selected bits, in their order after conversion, at particular SPAM-length-info register memory. Said L bits are the bits of the length token of said "00" header message. Automatically controller, 39, compares the  
30 information at said SPAM-length-info memory to preprogrammed token-comparison information and determines that said information at memory matches particular X-token information. (Said X-token information is different token-comparison  
35 information from the W-token information matched by the

110

length-token of the first message of example #1.) Said match causes controller, 39, automatically to select particular preprogrammed x-bits information that is bit-length-number information associated on a one to one basis with said X-5 token information and to place said x-bits information at said SPAM-length-info memory. The numeric value of said x-bits information is the MMS-L, the precise number of bits, after the last of said L bits, that remain in the meter-monitor segment associated with said L bits.

10 Then said transfer-a-00-header-message instructions cause controller, 39, to execute particular preprogrammed determine-command-information-word-length instructions. Said instructions cause controller, 39, to add a particular preprogrammed constant number that is the sum of H plus X  
15 plus L to the x-bits information at said SPAM-length-info memory. (Hereinafter, said constant is called "H+X+L".) In so doing, controller, 39, determines the number of bits in the command information of said "00" header message. Then controller, 39, divides the numeric information at said  
20 memory by the number of bits in one signal word and stores the quotient of said dividing at said SPAM-length-info memory. By determining said quotient, controller, 39, determines the number of signal words in said command information. (Said quotient may be an integer or a so-called  
25 "floating point number" that is a whole number plus a decimal fraction.)

Having determined said number of signal words, controller, 39, can determine whether or not the possibility exists that an instance of the aforementioned full signal  
30 word of padding bits follows the last signal word of said number of signal words. If said command information fills a whole number of signal words plus a decimal fraction, the last signal word in which command information occurs is not completely filled by command information bits. Padding bits  
35 that are MOVE bits fill out said signal word, and no

///

possibility exists that a full signal word of padding bits follows said signal word. On the other hand, if said command information fills a whole number of signal words exactly, the last signal word in which command information occurs is  
5 completely filled by command information bits. The possibility exists that said signal word may contain no MOVE bit information and that a full signal word of padding bits may follow said signal word.

To determine whether said possibility exists, said  
10 transfer-a-00-header-message instructions cause controller, 39, to execute particular preprogrammed evaluate-end-condition instructions. In a fashion well known in the art, said instructions cause controller, 39, to identify the largest integer that is less than or equal to the information  
15 at said SPAM-length-info memory and place information of said integer at particular working register memory. Then controller, 39, compares the information at said working memory to the information at said SPAM-length-info memory. (For the information of said largest integer to equal the  
20 information of said quotient means that said quotient is an integer, that said command information fills a whole number of signal words exactly, and that the possibility exists that a full signal word of padding bits does follow the last signal word in which command information occurs.) If the  
25 information at said working memory is equal to the information at said SPAM-length-info memory, said instructions cause controller, 39, to place "0" information at particular SPAM-Flag-working register memory. Otherwise said instructions cause controller, 39, to place "1"  
30 information at said memory.

Then said transfer-a-00-header-message instructions cause controller, 39, to execute particular preprogrammed calculate-number-of-words-to-transfer instructions. Automatically, controller, 39, compares the information at  
35 said SPAM-Flag-working memory to particular end-condition-

comparison information that is "0". (If the information at  
said SPAM-Flag-working memory is "0", said command  
information fills a whole number of signal words exactly;  
said whole number is the integer information at said working  
5 memory; but the last signal word of command information must  
be evaluated to ascertain whether it contains MOVE bit  
information.) Under control of said instructions, resulting  
in a match with said "0" information causes controller, 39,  
to subtract one (1) from the numeric value of the integer  
10 information at said working memory. (On the other hand, if  
the information at said SPAM-Flag-working memory is "1", said  
command information only partially fills the last of a whole  
number of signal words exactly; MOVE bits fill the remainder  
of the last of said words; and said whole number is one  
15 greater than said largest integer information that is at said  
working memory.) Under control of said instructions, not  
resulting in a match with said "0" information causes  
controller, 39, to add one to the numeric value of the  
integer information at said working memory.

20 Next said transfer-a-00-header-message instructions  
cause controller, 39, to execute particular preprogrammed  
commence-transfer instructions. Said instructions cause  
controller, 39, to transfer a particular number of signal  
words of said command information, starting with the signal  
25 word in which the first of said first H bits occurs and  
transferring said information in its order after conversion,  
signal word by signal word. Said number is the numeric value  
of the integer information at said working memory.

Finally, said transfer-a-00-header-message  
30 instructions cause controller, 39, to execute particular  
preprogrammed evaluate-padding-bits-? instructions that cause  
controller, 39, to compare the information at said SPAM-Flag-  
working memory to particular continue-? information that is  
"0".

35 Not resulting in a match means that, under control of

//3

said commence-transfer instructions, controller, 39, has transferred all command information of said "00" header message and no possibility exists that a full signal word of padding bits ends said message. Accordingly, not resulting  
5 in a match causes controller, 39, to complete said transfer-a-00-header-message instructions.

On the other hand, resulting in a match means that controller, 39, has transferred all but the last signal word of command information, and said word must be evaluated to  
10 ascertain whether it contains MOVE bit information.

Accordingly, resulting in a match causes controller, 39, to execute the aforementioned assess-padding-bit instructions. Said instructions cause controller, 39, to compare said last word to particular preprogrammed end?-EOFS-WORD information  
15 that is the information of one EOFS WORD. If no match results, said word is the last word of said message.

Otherwise, one full signal word of padding bits follows said word and ends said message. Accordingly, when said last word is compared to said EOFS WORD information, not resulting in a  
20 match causes controller, 39, to transfer just said last signal word, but resulting in a match causes controller, 39, to transfer said last signal word then the signal word, in said binary information, that is immediately after said signal word. In so doing, controller, 39, transfers the  
25 complete binary information of the message of the instance of header information at said SPAM-header memory and completes said transfer-a-00-header-message instructions.

Two specific cases illustrate the operation of said transfer-a-00-header-message instructions. One focuses on  
30 the "00" header message of Fig. 2H. The other focuses on the message of Fig. 2K. In either case, the signal words are eight-bit bytes, H equals two, X equals six, L equals two, and H+X+L equals ten. In both cases, controller, 39, is preprogrammed with token-comparison information, including  
35 particular 01-token information that is "01" and is

114

associated, on a one to one basis, with particular preprogrammed 01011-bits information that is the binary representation of eleven and particular 11-token information that is "11" and is associated, on a one to one basis, with  
5 particular preprogrammed 10110-bits information that is the binary representation of twenty-two. In both cases, when said instructions are invoked, information of the first H (that is, the first two) bits of the message being processed has been recorded at SPAM-header memory and information of  
10 the next X (that is the next six, the third through the eight bits) has been recorded at SPAM-exec memory. Thus said instructions process binary information that commences at the bit that is located immediately after the eighth bit of said message which eighth bit is the last of said X bits.

15 Fig. 2H shows one instance of a message that contains command information that fills a whole number of signal words plus a decimal fraction. Said command information fills two bytes plus five bits (that is, 2.625 bytes). Three padding bits that are MOVE bits have been added to the third byte of  
20 said message to fill out said byte.

When said transfer-a-00-header-message instructions are executed in the course of the processing of the message of Fig. 2H, said instructions cause processing to proceed in the following fashion.

25 Said process-length-token instructions are executed and cause controller, 39, to select the first two bits of said binary information immediately after said eighth bit and record said bits at said SPAM-length-info memory. Said two bits are "01", the length-token of said message. (After said  
30 bits are recorded at said memory, the information at said memory is "0000000000000001".) Automatically controller, 39, commences comparing the information at said SPAM-length-info memory to said token-comparison information. In the course of said comparing, controller, 39, automatically places at  
35 particular working register memory said 01-token information

//5

that is "01". (After said information is placed at said memory, the information at said memory is "0000000000000001".) Automatically, controller, 39, compares the information at said SPAM-length-info memory to the  
5 information at said working memory, and a match results. Said match causes controller, 39, automatically to select said 01011-bits information that is the binary representation of eleven and place said information at said SPAM-length-info memory. (Eleven, which is the numeric value of said 01011-  
10 bits information, is the MMS-L of said message.)

Then automatically said determine-command-information-word-length instructions are executed. Said instructions cause controller, 39, to add  $H+X+L$ , which is the binary representation of ten, to the information at said SPAM-  
15 length-info memory. In so doing, controller, 39, places at said SPAM-length-info memory the numeric value of the number of bits in the command information of said message--twenty-one (which is eleven plus ten). Then controller, 39, divides the numeric value information at said memory (twenty-one) by  
20 the number of bits in one byte (eight) and stores the quotient of said dividing (which quotient is 2.625 and is stored in a floating point fashion) at said SPAM-length-info memory. In so doing, controller, 39, determines that said command information occupies 2.625 bytes.

25 Next said evaluate-end-condition instructions are executed. Said instructions cause controller, 39, to identify the integer two (2) as the largest integer that is less than or equal to the 2.625 information that is at said SPAM-length-info memory and to place binary information of  
30 said integer, two (2), at said working register memory. Automatically controller, 39, compares said two (2) information at working memory to said 2.625 information at SPAM-length-info memory. Because the information at said working memory is not equal to the information at said SPAM-  
35 length-info memory, controller, 39, automatically places "1"

116

information at said SPAM-Flag-working register memory.

Then said calculate-number-of-words-to-transfer instructions are executed. Automatically, controller, 39, compares the information at said SPAM-Flag-working memory to  
5 said end-condition-comparison information that is "0", and no match results. (The fact that the information at said SPAM-Flag-working memory is "1", means that said command information only partially fills the last byte of said message, that MOVE bits fill the remainder of said byte, and  
10 that the number of bytes in said message is one greater than said integer information at said working memory.) Not resulting in a match causes controller, 39, to add one (1) to the numeric value two (2) that is the information at said working memory, thereby increasing the numeric value of said  
15 information at working memory to three (3).

Next said commence-transfer instructions are executed. Said instructions cause controller, 39, to transfer three (3) eight-bit bytes (which three (3) is the numeric value of the integer information at said working memory) of binary  
20 information, starting with the byte in which the first bit of said message occurs and transferring said information in its order after conversion, byte by byte. In so doing, controller, 39, transfers all information of said message to the addressed apparatus of said message.

25 Finally, said evaluate-padding-bits-? instructions are executed and cause controller, 39, to compare the "1" information at said SPAM-Flag-working memory to said continue-? information that is "0", and no match results. Not resulting in a match causes controller, 39, to complete  
30 said transfer-a-00-header-message instructions.

In this fashion, said transfer-a-00-header-message instructions cause controller, 39, to transfer the message of Fig. 2H to the addressed apparatus of said message.

By contrast, the second illustrative case of Fig. 2K  
35 shows a message that contains command information that fills

117

a whole number of signal words exactly and is followed by a full signal word of padding bits. The command information of said message fills four bytes. The last of said bytes contains only EOFs bits and is an EOFs WORD. Accordingly  
5 said last byte is followed by one full byte of padding bits which one byte is the fifth and last byte of said message.

Said transfer-a-00-header-message instructions cause the message of Fig. 2K, to be processed in the following fashion.

10 Said process-length-token instructions cause controller, 39, to select the ninth and tenth bits of said binary information and record said bits at said SPAM-length-info memory. Said two bits are the "11" length-token of said message, and after said bits are so recorded, the information  
15 at said memory is "0000000000000011". Automatically controller, 39, commences comparing said information at SPAM-length-info memory to said token-comparison information. Automatically controller, 39, places said 11-token information that is "11" at said working register memory,  
20 after which the information at said memory is "0000000000000011". Automatically, controller, 39, compares said information at SPAM-length-info memory to said information at said working memory, and a match results. Said match causes controller, 39, automatically to select  
25 said 10110-bits information that is the binary representation of twenty-two and place said information at said SPAM-length-info memory. (Twenty-two, which is the decimal equivalent value of said 10110-bits information, is the MMS-L of said message.)

30 Then said determine-command-information-word-length instructions cause controller, 39, to add H+X+L, which is the binary representation of ten, to the information at said SPAM-length-info memory, making the information at said SPAM-length-info memory the binary representation of thirty-two.  
35 Then controller, 39, divides information at said memory

118

(thirty-two) by the number of bits in one byte (eight) and stores the quotient of said dividing (which quotient is 4 and is stored in an integer fashion) at said SPAM-length-info memory. In so doing, controller, 39, determines that said 5 command information occupies 4 bytes exactly.

Next said evaluate-end-condition instructions cause controller, 39, to identify the integer four (4) as the largest integer that is less than or equal to the 4 information at said SPAM-length-info memory and to place 10 binary information of said integer, four (4), at said working register memory. Automatically controller, 39, determines that said four (4) information at working memory matches said 4 information at SPAM-length-info memory. Said match causes controller, 39, automatically to place "0" information at 15 said SPAM-Flag-working register memory.

Then said calculate-number-of-words-to-transfer instructions cause controller, 39, to determine that the information at said SPAM-Flag-working memory matches said end-condition-comparison information that is "0". Said match 20 causes controller, 39, to subtract one (1) from the numeric value, four (4), that is the information at said working memory, thereby decreasing the numeric value of said information at working memory to three (3).

Next said commence-transfer instructions cause 25 controller, 39, to transfer three (3) eight-bit bytes (which three (3) is the numeric value of the integer information at said working memory) of binary information, starting with the byte in which the first bit of said message occurs and transferring said information in its order after conversion, 30 byte by byte. In so doing, controller, 39, transfers all but the last byte of command information. Controller, 39, transfers the first, second, and third bytes. But the fourth byte, which is said last byte, remains untransferred.

Finally, said evaluate-padding-bits-? instructions 35 cause controller, 39, to determine that the "0" information

119

at said SPAM-Flag-working memory matches said continue-? information that is "0". Resulting in a match causes controller, 39, to execute said assess-padding-bit instructions. Said instructions cause controller, 39, to  
5 compare said last byte to said end-? EOFs WORD information. Because the fourth byte of the message of Fig. 2K is an EOFs WORD, a match results. Said match means that a full byte of padding bits follows said last byte of command information. Said match causes controller, 39, to transfer two bytes of  
10 binary information which bytes are the fourth and fifth bytes of said message (which fifth byte is the last signal word of said message). Then said instructions cause controller, 39, to complete said transfer-a-00-header-message instructions.

In this fashion, said transfer-a-00-header-message  
15 instructions cause controller, 39, to transfer the message of Fig. 2K to the addressed apparatus of said message.

In applicable fashions of said transfer-a-00-header-message instructions, controller, 39, transfers to SPAM-controller, 205C, the complete binary information of the  
20 message that contains the second combining synch command.

When controller, 39, completes said transfer-a-00-header-message instructions, automatically controller, 39, prepares all apparatus of decoder, 203, to receive a next SPAM message. Controller, 39, deactivates all output ports;  
25 determines that the information at said SPAM-header register memory does not match said cause-retention-of-exec information that is "11"; causes all apparatus of decoder, 203, to delete from memory all information of said binary information; then commences to wait for the binary  
30 information of a subsequent SPAM header.

At SPAM-controller, 205C, (and at the SPAM-controllers, 205C, of other URS microcomputers, 205), receiving the transferred binary information of said second message causes all apparatus automatically to process the  
35 information of said message in their preprogrammed fashions.

120

Automatically the EOFs valve of SPAM-controller, 205C, processes said information and transfers said information, signal word by signal word.

Receiving the header and execution segment of said  
5 second message causes SPAM-controller, 205C, to determine the controlled function or functions that said message instructs URS microcomputers, 205, to perform and to execute the instructions of said functions. Automatically, as said valve transfers information, SPAM-controller, 205C, selects the H  
10 first converted bits of said information, records said bits at said SPAM-header-@205 register memory, and determines that the information at said memory (which is the "00" header of said second message) does not match said 11-header-invoking-@205 information. No match results which causes controller,  
15 39, automatically to select the next X bits of said transferred binary information and record said bits at particular SPAM-exec-@205 register memory. Automatically SPAM-controller, 205C, compares the information at said SPAM-exec-@205 memory with said controlled-function-invoking-@205  
20 information. Said comparing results in a match with particular execute-conditional-overlay-at-205 information that causes SPAM-controller, 205C, to execute particular preprogrammed conditional-overlay-at-205 instructions.

Said instructions cause SPAM-controller, 205C, to  
25 execute "GRAPHICS ON" at the PC-MicroKey System of microcomputer, 205, if particular specified conditions are satisfied. To satisfy said conditions, the instance of image information at the video RAM of microcomputer, 205, (Fig. 1A) must be relevant to particular broadcast video programming transmitted immediately after the instance of broadcast  
30 programming in which said second message is embedded (Fig. 1B). More precisely, particular program unit and overlay number information specified for each instance must match. In the meter-monitor segment of the second combining synch  
35 command, said command conveys specified unit and number

/2/

information for said instance of broadcast programming. If, in a fashion described below, said specified information matches particular other unit and number information, said conditional-overlay-at-205 instructions cause SPAM-  
5 controller, 205C, so to execute "GRAPHICS ON". Accordingly, said second command is one example of a specified condition command.

In order to determine whether said specified information matches said other information, SPAM-controller,  
10 205C, must locate said specified information. More precisely, SPAM-controller, 205C, must locate two particular information fields of the meter-monitor segment of said second command. One is the program unit field whose information identifies uniquely the program unit of said  
15 "Wall Street Week" program. The other is the overlay number field whose information identifies uniquely the particular one of the overlays of said program that said command specifies and causes to be overlayed.

To locate said information, said conditional-overlay-at-205 instructions cause SPAM-controller, 205C, to execute the aforementioned evaluate-meter-monitor-format instructions. (Because said conditional-overlay-at-205 instructions are executed only by SPAM commands with "00" headers, comparing information at said SPAM-header-@205  
25 memory with header-identification-@205 information is unnecessary.) Said evaluate-meter-monitor-format instructions cause SPAM-controller, 205C, to select particular bits at particular predetermined locations in said transferred binary information and record said bits at  
30 particular SPAM-format register memory. Said bits are the bits of the meter-monitor format field of said command. Then, automatically, by comparing the information at said SPAM-format memory with preprogrammed format-specification information, SPAM-controller, 205C, determines that said  
35 information at memory matches particular information that

/22

invokes ~~particular~~ process-this-specific-format instructions. Automatically SPAM-controller, 205C, executes said instructions, and said instructions cause one particular offset-address number to be placed at particular SPAM-mm-format-@205 register memory at SPAM-controller, 205C. Said number specifies the address/location at the RAM of SPAM-controller, 205C, of the first bit of information that identifies the specific format of the meter-monitor segment of said second command.

10 Then said conditional-overlay-at-205 instructions cause SPAM-controller, 205C, to execute the aforementioned locate-program-unit instructions. Making reference to the information at said SPAM-mm-format memory, said instructions cause SPAM-controller, 205C, to select two particular  
15 preprogrammed binary numbers located at said RAM at two particular predetermined program-unit distances from said address/location and places said numbers, respectively, at the aforementioned first- and second-working register memories. Said numbers are respectively (1) the bit distance  
20 from the first bit of said transferred binary information to the first bit of said program unit field and (2) the bit length of said program field. Automatically SPAM-controller, 205C, selects particular information that begins at a bit distance after the first bit of said binary information,  
25 which bit distance is equal to the information at said first-working memory, and that is of a bit length equal to the information at said second-working memory. SPAM-controller, 205C, places said selected information at said first-working memory (thereby overwriting and obliterating the information  
30 previously there). In so doing, SPAM-controller, 205C, selects from the bits of said transferred binary information and records at said first-working memory the information of said program unit field.

Then said conditional-overlay-at-205 instructions  
35 cause SPAM-controller, 205C, to compare the information at

123

said first-working memory, which is the unique "program unit identification code" that identifies the program unit of said "Wall Street Week" program, to the information at the aforementioned SPAM-first-precondition register memory, which  
5 is the same unique code (having been transmitted to SPAM-controller, 205C, in the program unit field of the meter-monitor segment of the first combining synch command and so selected and recorded at said register memory under control of said evaluate-meter-monitor-format instructions and said  
10 locate-program-unit instructions when said instructions were executed by said load-run-and-code instructions in the course of the processing of said first message). A match results (which indicates that SPAM-controller, 205C, executed said load-run-and-code instructions under control of said first  
15 message.)

(At any subscriber station where information at first-working register memory fails to match information at SPAM-first-precondition register memory [indicating that the SPAM-controller, 205C, had not executed said instructions], said  
20 failing to match causes the SPAM-controller, 205C, of said station to execute particular preprogrammed instructions that cause the microcomputer, 205, of said station to clear all SPAM information from main and video RAMs and commence waiting for subsequent control instructions. Then the  
25 preprogrammed instructions of said SPAM-controller, 205C, cause SPAM-controller, 205C, to discard all information of transferred binary information of said second message and commence waiting for the binary information of a subsequent SPAM header.)

30 At the subscriber station of Fig. 3, said match of information at said first-working memory and information at SPAM-first-precondition memory, causes SPAM-controller, 205C, to continuing executing particular conditional-overlay-at-205 instructions. Said instructions cause SPAM-controller, 205C,  
35 to execute particular preprogrammed locate-overlay-number

124

instructions. Making reference to the information at said SPAM-mm-format memory, said instructions cause SPAM-controller, 205C, to select two particular preprogrammed binary numbers located at said RAM at particular  
5 predetermined overlay-number distances from said address/location and places said numbers, respectively, at said first- and second-working register memories. Said numbers are respectively (1) the bit distance from the first bit of said transferred binary information to the first bit  
10 of said overlay number field and (2) the bit length of said overlay field. Automatically SPAM-controller, 205C, selects particular information that begins at a bit distance after the first bit of said binary information, which bit distance is equal to the information at said first-working memory, and  
15 that is of a bit length equal to the information at said second-working memory. SPAM-controller, 205C, places said selected information at said first-working memory (thereby overwriting and obliterating the information previously there). In so doing, SPAM-controller, 205C, selects from the  
20 bits of said transferred binary information and records at said first-working memory the information of said overlay number field. (After the information of said overlay field is placed at said memory, the information at said memory is "00000001".)

25 Then said conditional-overlay-at-205 instructions cause SPAM-controller, 205C, to compare the information at said first-working memory to the "00000001" information at the aforementioned SPAM-second-precondition register memory. A match results (indicating that microcomputer, 205, has  
30 completed placing appropriate Fig. 1A image at video RAM).

(At any subscriber station where information at first-working register memory fails to match information at SPAM-second-precondition memory [indicating that the microcomputer, 205, has failed to complete so placing  
35 information at video RAM], said failing to match causes the

125

SPAM-controller, 205C, of said station to execute particular preprogrammed instructions that cause said SPAM-controller, 205C, to interrupt the operation of the CPU of said microcomputer, 205, in an interrupt fashion well known in the art, and transmit particular restore-efficiency instructions to said CPU that include information of the information at said first-working memory and that cause said microcomputer, 205, in a preprogrammed fashion discussed more fully below, to restore efficient operation.)

At the subscriber station of Fig. 3 (and at URS microcomputers, 205, at other subscriber stations where information at first-working memory matches information at SPAM-second-precondition memory), said match causes SPAM-controller, 205C, to continue executing particular conditional-overlay-at-205 instructions at a particular instruction. Said instruction causes SPAM-controller, 205C, to execute "GRAPHICS ON" at said PC-MicroKey System. In so doing, SPAM-controller, 205C, completes said conditional-overlay-at-205 instructions and the controlled functions of the second combining synch command.

Having completed said controlled functions, automatically SPAM-controller, 205C, prepares to receive the next instance of SPAM message information. Automatically, SPAM-controller, 205C, determines that the information at said SPAM-header-@205 register memory does not match said cause-retention-of-exec information that is "01"; causes all apparatus of SPAM-controller, 205C, to delete from memory all information of said transferred binary information; and commences waiting to receive the binary information of a subsequent SPAM header.

In the foregoing fashion and as described in "One Combined Medium" above, said transferred information of the second combining synch command causes microcomputer, 205, to combine the programming of Fig. 1A and of Fig. 1B and transmit said combined programming to monitor, 202M, where

Fig. 1C is displayed.

126

OPERATING S. P. SYSTEMS ... EXAMPLE #1 (THIRD MESSAGE)

Subsequently, the embedded information of the third message, which conveys the third combining synch command, is transferred from divider, 4, to decoder, 203.

In the same fashion that applied to the first and second messages, receiving said embedded information causes decoder, 203, automatically to detect, check, correct as necessary, convert said information into binary information of said third message; to process and transfer said binary information at the EOFS valve of controller, 39; and then to process the header and execution segment information in said binary information at controller, 39.

Receiving said header and execution segment information causes controller, 39, to determine that said message is addressed to URS microcomputers, 205, and to transfer said message accordingly. Receiving the first H converted bits of said binary information from said valve causes controller, 39, to select and record said H bits (the "10" header of the third combining synch command which designates a SPAM command with only an execution segment) at said SPAM-header register memory then determine that the information at said SPAM-header memory does not match said "11" information. Not resulting in a match causes controller, 39, to process the next X received bits as the execution segment of a SPAM command. Receiving the next X bits of said binary information from said valve causes controller, 39, to select and record said next X bits (the execution segment of the third combining synch command) at said SPAM-exec register memory, compare the information at said SPAM-exec memory to said controlled-function-invoking information, determine that said information at memory matches particular preprogrammed this-message-addressed-to-205 information that invokes the aforementioned transfer-to-

127

205 instructions, and execute said instructions.

Automatically controller, 39, activates the output port that outputs to SPAM-controller, 205C; compares said information at SPAM-header memory to said header-identification

5 information; and determines that said information at memory matches particular "10" information. Said match causes controller, 39, automatically to execute particular preprogrammed transfer-a-10-header-message instructions.

A "10" header distinguishes a message that is  
10 constituted only of first priority segments. At any given time, any given instance of "10" header message command information is of one constant binary length--the aforementioned header+exec constant length. (Hereinafter, said length is called "H+X" and is the sum of H plus X.) No  
15 length token information is processed, but it may be necessary to execute the aforementioned assess-padding-bit instructions to determine whether a full signal word of padding follows the last signal word in which command information occurs.

20 Said transfer-a-10-header-message instructions transfer a "10" header message by executing many of the preprogrammed instructions executed by the aforementioned transfer-a-00-header-message instructions that controlled the transferring of the "00" header second message of example #1.

25 Because length token information is not processed, said transfer-a-10-header-message instructions do not cause execution of said process-length-token instructions.

Because each instance of "10" header message command information is of said one constant binary length, H+X, said  
30 transfer-a-10-header-message instructions do not cause execution of said determine-command-information-word-length instructions. Instead, said transfer-a-10-header-message instructions include particular preprogrammed 10-header-word-length information that is described more fully below.

35 Just as with "00" header messages, the the possibility

128

can exist that a full signal word of padding bits may follow the last signal word of command information of a "10" header message. If H+X bits of binary information fill a whole number of signal words plus a decimal fraction, the last 5 signal word of command information of any given instance of a "10" header message is not completely filled by command information bits. Padding bits that are MOVE bits fill out said word, and no possibility exists that a full word of padding bits follows said word. But if H+X bits fill a whole 10 number of signal words exactly, the last signal word of command information is completely filled by command information bits. Said word may contain no MOVE bit information, and a full signal word of padding bits may follow said word.

15 Because each instance of "10" header message command information is of said one length, said transfer-a-10-header-message instructions do not cause execution of said evaluate-end-condition instructions to determine whether said possibility exists. Instead, said transfer-a-10-header- 20 message instructions include particular preprogrammed 10-header-end-condition information. At those times when H+X bits of binary information fill a whole number of signal words exactly, said information is the binary value of zero. At all other times, said information is the binary value of 25 one.

Likewise, because each instance of "10" header message command information is of said one length, said transfer-a-10-header-message instructions do not cause execution of said calculate-number-of-words-to-transfer instructions. Instead, 30 at any given time said 10-header-word-length information is preprogrammed number information that applies to every instance of "10" header message information. At those times when H+X bits of binary information fill an integer number of signal words exactly and a full signal word of padding bits 35 may follow the last signal word in which command information

129

occurs, said 10-header-word-length information is, itself, and integer that equals said integer number minus one. In the preferred embodiment where signal words are eight-bit bytes said 10-header-word-length information equals  
5 (  $H+X / 8$  ) - 1. At those times when  $H+X$  bits of binary information do not fill a whole number of signal words exactly and the quotient of  $H+X$  divided by the number of bits in a signal word is a whole number plus a decimal fraction, said 10-header-word-length information equals the smallest  
10 integer larger than said quotient.

The first set of preprogrammed instructions that said transfer-a-10-header-message instructions and said transfer-a-00-header-message instructions have in common are said commence-transfer instructions. But before said transfer-a-  
15 10-header-message instructions can execute said commence-transfer instructions, said 10-header-word-length information and said 10-header-end-condition information must be at particular locations. Accordingly, when executed said transfer-a-10-header-message instructions cause controller,  
20 39, to place information of said 10-header-word-length information at the aforementioned particular working register memory and information of said 10-header-end-condition information at the aforementioned SPAM-Flag-working register memory.

25 Next said transfer-a-10-header-message instructions cause controller, 39, to execute said commence-transfer instructions. Said instructions cause controller, 39, to transfer a particular number of signal words of said command information, starting with the signal word in which the first  
30 of said first  $H$  bits occurs and transferring said information in its order after conversion, signal word by signal word. Said number is the numeric value of the integer information at said working memory.

Finally, said transfer-a-10-header-message  
35 instructions cause controller, 39, to execute said evaluate-

/30

padding-bits-? instructions that cause controller, 39, to compare the information at said SPAM-Flag-working memory to said continue-? information that is "0".

Not resulting in a match means that the last signal  
5 word in which command information occurs contains at least one MOVE bit of padding and that said 10-header-word-length information is the length of every instance of a "10" header message. Accordingly, not resulting in a match causes controller, 39, to end execution of said transfer-a-10-  
10 header-message instructions.

On the other hand, resulting in a match means that controller, 39, has transferred all but the last signal word of command information, and said word must be evaluated to ascertain whether it contains MOVE bit information.  
15 Accordingly, resulting in a match causes controller, 39, to execute said assess-padding-bit instructions. Said instructions cause controller, 39, to compare said last word to said end-?-EOFS-WORD information. If no match results, said word is the last word of said message. Otherwise, one  
20 full signal word of padding bits follows said word and ends said message. Accordingly, not resulting in a match causes controller, 39, to transfer just said last signal word, but resulting in a match causes controller, 39, to transfer said last signal word then the signal word, in said binary  
25 information, that is immediately after said signal word. In so doing, controller, 39, transfers the complete binary information of the message of the instance of header information at said SPAM-header memory and completes said transfer-a-10-header-message instructions.

The case of the "10" message of Fig. 2J illustrates  
30 the operation of said transfer-a-10-header-message instructions. As with the "00" messages of Fig. 2H and Fig. 2K, signal words are eight-bit bytes, H equals two, and X equals six. Hence, H+X equals eight. Accordingly,  
35 controller, 39, is preprogrammed with 10-header-word-length

/3/

information that is integer information of  $(8 / 8) - 1$ . More precisely, said 10-header-word-length information is integer information of zero. And because H+X bits of binary information fill a whole number of signal words exactly, 5 controller, 39, is preprogrammed with 10-header-end-condition information that is the binary value of zero.

Like Fig. 2K, Fig. 2J shows a message that contains command information that fills a whole number of signal words exactly. The command information of said message fills one 10 byte, and said byte is the last byte of said command information. As Fig. 2J shows, said last byte contains MOVE bit information. Accordingly said last byte is not followed by one full byte of padding bits. The one byte of said message is the last byte of said command information and the 15 last byte of said message.

Said transfer-a-10-header-message instructions cause the message of Fig. 2J, to be processed in the following fashion.

Executing said instructions causes controller, 39, to 20 place information of said 10-header-word-length information at said particular working register memory and information of said 10-header-end-condition information at said SPAM-Flag-working register memory. (After said 10-header-end-condition information is placed at said SPAM-Flag-working memory, the 25 information at said memory may be "0" or "00000000".)

Next said commence-transfer instructions cause controller, 39, to transfer zero (0) eight-bit bytes (which zero (0) is the numeric value of the integer information at said working memory) of binary information. (In other words, 30 controller, 39, transfers no information.) In so doing, controller, 39, transfers all but the last byte of command information. The one byte of said message, which is said last byte, remains untransferred.

Then said evaluate-padding-bits-? instructions cause 35 controller, 39, to determine that the zero information at

/32

said SPAM-Flag-working memory matches said continue-? information that is "0". Resulting in a match causes controller, 39, to execute said assess-padding-bit instructions. Said instructions cause controller, 39, to 5 compare said last byte to said end-?-EOFS-WORD information. Because the one byte of the message of Fig. 2J contains MOVE bit information, no match results. Not resulting in a match means that said one byte is the last byte of said message. Automatically, not resulting in a match causes controller, 10 39, to transfer one byte of binary information which byte is said one byte. Then said instructions cause controller, 39, to complete said transfer-a-10-header-message instructions.

In this fashion, said transfer-a-10-header-message instructions cause controller, 39, to transfer the message of 15 Fig. 2J to the addressed apparatus of said message.

In applicable fashions of said transfer-a-10-header-message instructions, controller, 39, transfers to SPAM-controller, 205C, the complete binary information of the message that contains the third combining synch command.

20 When controller, 39, completes said transfer-a-10-header-message instructions, automatically controller, 39, prepares all apparatus of decoder, 203, to receive a next SPAM message. Controller, 39, deactivates all output ports; determines that the information at said SPAM-header register 25 memory does not match said cause-retention-of-exec information that is "01"; causes all apparatus of decoder, 203, to delete from memory all information of said binary information; then commences to wait for the binary information of a subsequent SPAM header.

30 At SPAM-controller, 205C, (and at the SPAM-controllers, 205C, at other URS microcomputers, 205), receiving the transferred binary information of said third message causes all apparatus automatically to process the information of said message in their preprogrammed fashions.

35 Automatically the EOFS valve of SPAM-controller, 205C,

133

processes said information and transfers said information, signal word by signal word.

Receiving the header and execution segment of said third message causes SPAM-controller, 205C, to identify and  
5 execute the controlled function or functions that said message instructs URS microcomputers, 205, to perform. Receiving the first H converted bits of said transferred binary information from said valve causes SPAM-controller, 205C, to select and record said H bits at said SPAM-header-  
10 @205 register memory; determine that the information at said memory does not match said 11-header-invoking information; then process the next X received bits of said binary information as the execution segment of a SPAM command. Receiving said next X bits causes SPAM-controller, 205C, to  
15 select and record said X bits at said SPAM-exec-@205 register memory; compare the information at said memory with said controlled-function-invoking-@205 information; determine that said information at memory matches particular cease-overlay information that causes SPAM-controller, 205C, to execute  
20 particular preprogrammed cease-overlaying-at-205 instructions; and execute said instructions.

Said instructions cause SPAM-controller, 205C, to execute "GRAPHICS OFF" at said PC-MicroKey System then transmit a particular clear-and-continue instruction to the  
25 CPU of microcomputer, 205, the function of which instruction is described more fully below. In so doing, SPAM-controller, 205C, completes said cease-overlaying-at-205 instructions.

(Because said cease-overlaying-at-205 instructions are executed only by SPAM commands with "10" headers, comparing  
30 information at said SPAM-header-@205 memory with header-identification-@205 information is unnecessary.)

Having completed the controlled functions of said second message, automatically SPAM-controller, 205C, prepares to receive the next instance of SPAM message information. Automatically, SPAM-controller, 205C, determines that the  
35

134

information at said SPAM-header-@205 register memory does not match said cause-retention-of-exec-@205 information that is "01"; causes all apparatus of SPAM-controller, 205C, to delete from memory all information of said transferred binary 5 information; and commences waiting to receive the binary information of a subsequent SPAM header.

In the foregoing fashion and as described in "One Combined Medium" above, said transferred information of the third combining synch command causes microcomputer, 205, to 10 cease combining the programming of Fig. 1A and of Fig. 1B and commence transmitting to monitor, 202M, only the composite video programming received from divider, 4, (which causes monitor, 202M, to commence displaying only said video programming) and to continue processing in a predetermined 15 fashion (which fashion may be determined by the aforementioned program instruction set).

#### OPERATING S. P. SYSTEMS ... EXAMPLE #1 (A FOURTH MESSAGE)

The "One Combined Medium" example does not include an 20 instance of a SPAM message with a "11" header, but decoder, 203, is preprogrammed to process such messages.

A fourth message of example #1 illustrates the processing of a "11" header message.

Immediately after transmitting the third message of 25 example #1, the program originating studio of the "Wall Street Week" program embeds and transmits a fourth message. Said message consists of an "11" header followed immediately by an information segment containing a second program instruction set. More precisely, the first two bits of the 30 first signal word of said message are said "11" header, and the remaining bits of said signal word are padding bits. The first signal word of said information segment is the signal word immediately after said first word. And immediately after the last signal word of said segment, an end of file 35 signal is transmitted that ends said message.

/35

Subsequently, the embedded information of said fourth message is transferred from divider, 4, to decoder, 203.

Receiving the embedded information of said message causes decoder, 203, automatically to detect, check, correct as necessary, and convert said information into binary information of said fourth message; to process and transfer said binary information at the EOFs valve of controller, 39; then to process the header in said binary information.

Receiving said header causes controller, 39, to determine that said message is addressed to URS microcomputers, 205, and to transfer said message accordingly. Receiving the first H converted bits of said binary information from said valve causes controller, 39, to select and record said H bits (said "11" header) at said SPAM-header register memory then determine that the information at said SPAM-header memory matches said 11-header-invoking information that is "11". Said match causes controller, 39, to execute particular preprogrammed process-11-header-message instructions.

Said instructions cause controller, 39, to execute controlled functions as if the information at said SPAM-last-01-header-exec register memory were the execution segment information of said "11" header message. Automatically, said instructions cause controller, 39, to compare the information at said SPAM-last-01-header-exec memory (which information is the execution segment of the first combining synch command) with said controlled-function-invoking information. Automatically, controller, 39, determines that said information at memory matches particular preprogrammed this-message-addressed-to-205 information that invokes the aforementioned transfer-to-205 instructions. Automatically controller, 39, executes said instructions; activates the output port that outputs to SPAM-controller, 205C; and determines that said information at SPAM-header memory matches particular "11" information. Said match causes

136

controller, 39, automatically to execute said transfer-a-01-or-a-11-header-message instructions.

An "11" header distinguishes a message that contains lowest priority information. Just like an "01" header message, each instance of a message with a "11" header ends with an end of file signal. Accordingly, said instructions cause controller, 39, to transfer said fourth message in precisely the same fashion that applied to the transfer of the first message of example #1. Automatically controller, 39, commences transferring the binary information of said fourth message, starting with said first H bits, and continues so transferring, as said binary information is outputted by said EOFs valve, until said valve detects the end of file signal of said message and causes EOFs-signal-detected information to be inputted to the CPU of controller, 39.

In due course and in precisely the fashion of the first message of example #1, said valve detects the eleven EOFs WORDs of said end of file signal and causes transmission of said EOFs-signal-detected information to controller, 39, which causes controller, 39, to transmit said transmit-and-wait instruction to said valve. Said instruction causes said valve to perform all the functions caused by the corresponding instruction of said first message, including transferring one complete end of file signal (which information is automatically transferred to SPAM-controller, 205C). In this fashion, controller, 39, transfers the complete information of said fourth message to the addressed apparatus of said message--the SPAM-controller, 205C.

Having transferred the binary information of said fourth message, controller, 39, prepares all apparatus of decoder, 203, to receive the next instance of SPAM message information in precisely the fashion of said first message with one exception. Unlike said first message which had an "01" header and contained a command with an execution

/37

segment, said fourth message has an "11" header and contains no execution segment information. Accordingly, receiving said fourth message does not cause controller, 39, to record information at said SPAM-last-01-header-exec memory. When 5 controller, 39, compares the information at said SPAM-header register memory to said cause-retention-of-exec information that is "01", no match results. The information that was at said memory when said message was received--specifically, the execution segment of the first message--remains at said 10 memory.

(If no information were to exist at said SPAM-last-01-header-exec memory when information at said memory is compared with said controlled-function-invoking information, controller, 39, would detect the absence of said information 15 in a predetermined fashion and, in the fashion described above in the description of the first message, would cause all apparatus of decoder, 203, to discard all message information until an end of file signal were received and discarded then would process the first H converted bits of 20 the next received binary information as a subsequent SPAM header.)

At SPAM-controller, 205C, (and at SPAM-controllers, 205C, of URS microcomputers, 205) receiving the transferred binary information of said fourth message causes all 25 apparatus automatically to process the information of said message in the preprogrammed fashions of said apparatus.

Automatically the EOFs valve of SPAM-controller, 205C, processes and transfers said information until an end of file signal is detected.

30 Receiving the header of said fourth message causes SPAM-controller, 205C, to determine the controlled function or functions that said message instructs URS microcomputers, 205, to perform and to execute the instructions of said functions. Receiving the first H bits of said transferred 35 binary information from said valve causes SPAM-controller,

/38

205C, to select and record said first H bits (said "11" header) at said SPAM-header-@205 register memory then determine that said information at SPAM-header-@205 memory matches said 11-header-invoking-@205 information that is 5 "11". Said match causes SPAM-controller, 205C, to execute particular preprogrammed process-11-header-message-@205 instructions.

Said instructions cause SPAM-controller, 205C, to execute controlled functions as if the information at said 10 SPAM-last-01-header-exec-@205 register memory (which information is the execution segment of the first combining synch command) were the execution segment information of said "11" header message. Automatically, said instructions cause SPAM-controller, 205C, to compare the information at said 15 memory with said controlled-function-invoking information-@205. A match results with said execute-load-run-and-code information, causing SPAM-controller, 205C, automatically to execute said load-run-and-code instructions. As with said first message, said instructions control the loading, at the 20 main RAM of microcomputer, 205, and running of the information segment information that follows said H bits, which information is said second program instruction set.

To locate, in said transferred binary information, the first bit of said information, said instructions cause SPAM- 25 controller, 205C, to compare the information at said SPAM-header-@205 memory with said header-identification-@205 information and determine that said information at memory matches particular "11" information. In other words, to locate said bit, SPAM-controller, 205C, must process only the 30 information associated with an "11" header. Accordingly, said match causes SPAM-controller, 205C, automatically to execute particular preprogrammed prepare-to-load-11-header-message instructions.

At any given time, each instance of header information 35 is of one constant binary length--H bits--that either does or

139

does not fill a whole number of signal words exactly. If H bits do not, the last signal word of any given instance of a "11" header message header is not completely filled with header information, and padding bits that are MOVE bits fill out said signal word. But if H bits do fill a whole number of signal words exactly, the last signal word in which header information may contain no MOVE bit information, in which case one full word of padding bits follows said signal word and precedes the first information segment signal word of said message.

To locate said first bit, said prepare-to-load-11-header-message instructions include particular preprogrammed 11-header-word-length information and particular preprogrammed 11-header-end-condition information. At those times when H bits of binary information fill a whole number of signal words exactly, said 11-header-word-length information is the largest integer that is less than said whole number, and said end-condition information is the binary value of zero. At those times when H bits do not fill a whole number of signal words exactly, said 11-header-word-length information is the smallest integer larger than the number of signal words that said H bits do fill, and said header-end-condition information is the binary value of one.

When executed, said prepare-to-load-11-header-message instructions cause SPAM-controller, 205C, to place information of said 11-header-word-length at particular first-working-@205 register memory then compare said 11-header-end-condition information to particular preprogrammed information that is "0".

Not resulting in a match means that the last signal word in which header information occurs contains at least one MOVE bit of padding and that said 11-header-word-length information is the length of every instance of a "11" header information. Accordingly, not resulting in a match causes SPAM-controller, 205C, to execute of particular preprogrammed

140

commence-loading-11-header-message instructions.

On the other hand, resulting in a match means that the last signal word of header information must be evaluated to ascertain whether it contains MOVE bit information.

5 Accordingly, resulting in a match causes SPAM-controller, 205C, starting with the first signal word of said transferred binary information, to skip a number of signal words of said information, which number is the number of the integer information at said first-working-@205 memory. In so doing,

10 SPAM-controller, 205C, skips every signal word of header information but said last word. Then, automatically, said instructions cause SPAM-controller, 205C, to compare said last word to said particular preprogrammed EOFs-WORD information. If no match results, said word is the last word

15 of said message. Otherwise, one full signal word of padding bits follows said word and ends said message. Accordingly, not resulting in a match causes SPAM-controller, 205C, to add binary information of one to said integer information at said first-working-@205 memory, but resulting in a match causes

20 SPAM-controller, 205C, to add binary information of two to said integer information at said first-working-@205 memory. Then, automatically, SPAM-controller, 205C, executes said commence-loading-11-header-message instructions.

When executed, said commence-loading-11-header-message

25 instructions cause SPAM-controller, 205C, starting with the first signal word of said transferred binary information, to skip a number of signal words, which number is the number of the integer information at said first-working-@205 memory. In so doing, SPAM-controller, 205C, skips every signal word

30 of header information. Then said instructions instruct SPAM-controller, 205C, to commence loading information at the main RAM of microcomputer, 205, starting with the first signal word after the last skipped signal word, and cause SPAM-controller, 205C, to commence executing said load-run-and-

35 code instructions at a particular instruction.

141

Starting at said instruction, said load-run-and-code instructions cause SPAM-controller, 205C, to instruct microcomputer, 205, to commence receiving information from SPAM-controller, 205C, and loading said information at 5 particular main RAM, in a fashion well known in the art.

Thereafter, said instructions cause SPAM-controller, 205C, to process said fourth message in precisely the same fashion that applied to the first message of example #1.

Said load-run-and-code instructions cause SPAM- 10 controller, 205C, to commence transferring information to microcomputer, 205, beginning with said first signal word, and transfer the remaining signal words of said transferred binary information, signal word by signal word, until said valve detects the end of file signal of said message and 15 causes EOFs-signal-detected information to be inputted to the CPU of SPAM-controller, 205C. As microcomputer, 205, receives said information, it loads said information at particular main RAM.

In due course, said valve transfers the last signal 20 word of the information segment of said fourth message, which is the last signal word of said program instruction set, which causes SPAM-controller, 205C, to transfer said word to microcomputer, 205, and microcomputer, 205, to load said word at said RAM.

25 In this fashion, receiving the information of said fourth message causes the apparatus of the subscriber station of Fig. 3 to load said program instruction set at the main RAM of microcomputer, 205, (and other stations to load said set at other main RAMs).

30 Then, in precisely the fashion of the first message of example #1, said valve detects the eleven EOFs WORDs of said end of file signal and causes transmission of said EOFs-signal-detected information to SPAM-controller, 205C which causes SPAM-controller, 205C, to cause microcomputer, 205, to 35 cease loading information at said RAM and execute the

142

information so loaded as the machine executable code of one job. Continuing in said fashion, SPAM-controller, 205C, transmits said discard-and-wait instruction to said valve which causes said valve to set the information at said EOFS  
5 WORD Counter to "00000000" and to process no next inputted information until a control instruction is received from SPAM-controller, 205C.

Then the code portion of said said load-run-and-code instructions cause SPAM-controller, 205C, to operate in a  
10 fashion that differs from the fashion of said first message. The instructions of said portion cause SPAM-controller, 205C, to compare the information at said SPAM-header memory to said load-run-and-code information that is "01". No match results because the header of said fourth message is "11" (which  
15 means that said message contains no meter-monitor information). Not resulting in a match causes SPAM-controller, 205C, automatically to skip the remaining instructions of said code portion and complete said load-run-and-code instructions without placing any program unit field  
20 information at said SPAM-first-precondition register memory. Accordingly, the program unit information of said "Wall Street Week" program that was caused to be placed at said SPAM-first-precondition memory by the first combining synch command remains at said memory.

25 Having processed the binary information of said fourth message, SPAM-controller, 205C, prepares all apparatus of decoder, 203, to receive the next instance of SPAM message information in precisely the fashion of said first message with one exception. Receiving said fourth message does not  
30 cause SPAM-controller, 205C, to record information at said SPAM-last-01-header-exec memory-@205. When SPAM-controller, 205C, compares the information at said SPAM-header-@205 memory to said cause-retention-of-exec-@205 information that is "01", no match results. The information that was at said  
35 memory when said message was received--specifically, the

143

execution segment of the first message--remains at said memory.

In this fashion, the subscriber station of Fig. 3 processes a message with an "11" header.

5

#### OPERATING SIGNAL PROCESSOR SYSTEMS ... EXAMPLE #2

In example #2, the first and third messages of the "Wall Street Week" combining are transmitted just as in example #1, but the second message is partially encrypted.

10 The second message conveys the second combining synch command. In example #2, before said message is embedded at the program originating studio and transmitted, the execution segment of said command and all of the meter-monitor segment except for the length-token are encrypted, using standard  
15 encryption techniques, well known in the art, that encrypt binary information without altering the number of bits in said information. Partially encrypting the second message in this fashion leaves the cadence information of said message unencrypted. In other words, the "00" header, the length-  
20 token, and any padding bits added at the end of said message remain unencrypted. Said message is only partially encrypted in order to enable subscriber stations that lack capacity to decrypt said message to process the cadence information of said message accurately.

25 In example #2, the encryption of said execution segment is done in such a fashion that, after encryption, said segment is identical to a particular execution segment that addresses URS signal processors, 200, and instructs said processors, 200, to use a particular decryption key J and  
30 decrypt the message in which said segment occurs.

Because said message is encrypted, its meter-monitor segment contains a sixth field, a meter instruction field. Accordingly, the length of the second message, the number of bits in its meter-monitor segment and the numeric value of  
35 MMS-L is greater in example #2 than in example #1.

144

As described above in "One Combined Medium," before any messages of the "Wall Street Week" programming are transmitted, control invoking instructions are embedded at said program originating studio and transmitted to all  
5 subscriber stations. Among said instructions are particular ones that command URS microcomputers, 205, to set their PC-MicroKey Model 1300 Systems to the "Graphics Off" mode. Thus, at the outset of example #2, all PC-MicroKey 1300s are in the "Graphics Off" mode, and no microcomputer, 205, is  
10 transmitting combined information of video RAM and received composite video to its associated monitor, 202M. As will be seen, this fact has particular relevance in example #2.

In example #2, the first message of the "Wall Street Week" program is transmitted precisely as in the example #1  
15 and causes precisely the same activity at subscriber stations. At each station, a microcomputer, 205, enters appropriate Fig. 1A image information at particular video RAM.

When decoder, 203, receives the embedded information  
20 of the second message of example #2, decoder, 203, processes and transfers said information in the same fashion that applied to the second message of example #1 with three exceptions.

First, controller, 39, determines that the second  
25 message of example #2 is addressed to URS signal processors, 200, rather than URS microcomputers, 205, and transfers the binary information of said message accordingly. When controller, 39, compares the information at SPAM-exec memory, which is the encrypted execution segment information of the  
30 second message of example #2, with controlled-function-invoking information, said information at memory does not match the this-message-addressed-to-205 information matched in example #1. Rather said information at memory matches particular preprogrammed this-message-addressed-to-200  
35 information that invokes preprogrammed transfer-to-200

145

instructions. Controller, 39, executes said instructions, and rather than activating the output port that outputs to SPAM-controller, 205C, said instructions cause controller, 39, to activate the output port that outputs to  
5 buffer/comparator, 8, of signal processor, 200.

Then, subsequently, when said process-length-token instructions cause controller, 39, to compare the information at SPAM-length-info memory, which is the length-token information of said second message of example #2, to  
10 token-comparison information, said information at memory does not match the X-token information matched by the length-token of the second message of example #1. Rather, said information at memory matches particular preprogrammed Y-token information associated with particular preprogrammed  
15 y-bits information whose numeric value is the MMS-L of the second message of example #2. Said match causes controller, 39, automatically to select said y-bits information and place said information at said SPAM-length-info memory. Thus controller, 39, processes a value of MMS-L that is different  
20 from the value processed in example #1.

Finally, because the second message of example #2 is longer than the second message of example #1 and the MMS-L of example #2 is greater than the MMS-L of example #1, when said transfer-a-00-header-message instructions control the  
25 transfer of the the second message of example #2 to signal processor, 200, said instructions transfer a longer message.

In all other respects, controller, 39 processes and transfers the second message of example #2 just as it processed and transferred the second message of example #1.  
30 And when the transfer of the second message of example #2 is complete, controller, 39, automatically deactivates all output ports, deletes all received information of said message from memory, and commences waiting for the binary information of a subsequent SPAM header.

35 Receiving the binary signal information of said second

146

message causes buffer/comparator, 8, automatically to execute a decryption sequence at signal processor, 200, that is fully automatic and for which all apparatus are preprogrammed.

Receiving said information causes buffer/comparator, 5 8, first, to place said information at a particular received signal location at buffer/comparator, 8, then to compare a particular portion the first X bits immediately after the first H bits of said binary information (which X bits are the executions segment of said message) to particular .  
10 preprogrammed comparison information in its automatic comparing fashion. (Buffer/comparator, 8, is preprogrammed with information that identifies said portion.) A match results with particular comparison information that is the bit image of particular SPAM execution segment information  
15 that instructs URS signal processors, 200, to decrypt. Said match causes buffer/comparator, 8, to transfer to controller, 20, particular decrypt-this-message information that includes the memory position of the first bit location of said particular received signal location and information of the  
20 header and execution segment in said binary signal information. Receiving said information causes controller, 20, to compare the information of said execution segment to particular preprogrammed controlled-function-invoking-@200 information and determine a match with particular decrypt-  
25 with-key-J information that instructs controller, 20, to decrypt the received binary signal information with decryption key J.

(At subscriber stations whose URS signal processors, 200, are not preprogrammed with information of said key J,  
30 the information of said execution segment fails to match any controlled-function-invoking-@200 information. Said failures to match cause the controllers, 20, of said stations automatically to discard all information transferred by the buffer/comparators, 8; to cause said buffer/comparators, 8,  
35 to discard all received information of said second message;

/47

and to cause said controllers, 20, and said buffer/comparators, 8, to commence processing in the conventional fashion.)

(It is to facilitate SPAM processing at said stations 5 that are not preprogrammed with necessary decryption key information that the cadence information of an otherwise encrypted SPAM message must remain unencrypted. Were either the header or length-token or any padding bits of said second message encrypted, the decoders, 203, and signal processors, 10 200, of said stations could process the information of the execution segment correctly but would be unable to locate the last bit of said second message and the header of the following message. Effective SPAM processing would cease and not resume until the apparatus at said stations detected an 15 unencrypted end of file signal. Until that time, converted binary information could continue to invoke processing at said stations but said processing would be haphazard and almost certainly undesirable.)

Because the subscriber station of Fig. 3 is 20 preprogrammed with all information needed to decrypt said second message, the aforementioned match with said decrypt-with-key-J information causes controller, 20, to execute particular preprogrammed decrypt-with-J instructions. Among said preprogrammed instructions is key information of J, and 25 said instructions cause controller, 20, automatically to select and transfer said key information to decryptor, 10.

Decryptor, 10, receives said key information and automatically commences using it as its key for decryption.

Then said decrypt-with-J instructions cause 30 controller, 20, to activate the output capacity of buffer/comparator, 8, that outputs to decryptor, 10; to compare said information of the header transferred from buffer/comparator, 8, to particular preprogrammed header-identification-@200 information; and to determine that 35 said information of the header matches particular "00" header

148

information. Said match causes controller, 20, automatically to invoke particular preprogrammed decrypt-a-00-header-message instructions.

Controller, 20, is preprogrammed with information of  
5 H, X, L, and H+X; with process-length-token, determine-  
command-information-word-length, evaluate-end-condition,  
calculate-number-of-words-to-transfer, evaluate-padding-  
bits-? instructions; and with token-comparison, W-token, X-  
token, Y-token, w-bits, x-bits, and y-bits information.  
10 Using preprogrammed information and instructions as required,  
said decrypt-a-00-header-message instructions transfer the  
received binary information of said second message from  
buffer/comparator, 8, to decryptor, 10, in the same fashion  
that the aforementioned transfer-a-00-header-message  
15 instructions controlled the transfer of the information of  
said message from controller, 39, to buffer/comparator, 8.

Under control of said decrypt-a-00-header-message  
instructions, said process-length-token instructions cause  
controller, 20, to select the L bits of said binary signal  
20 information that begin at the first bit location that is H+X  
bit locations following the memory position of the first bit  
location of said particular received signal location at  
buffer/comparator, 8. Said L bits are the length token of  
said second message. Automatically controller, 20, compares  
25 the information of said L bits to token-comparison  
information and determines a match with preprogrammed Y-token  
information. Said match causes controller, 20, automatically  
to select y-bits information and process said information as  
the numeric value of MMS-L. Next said determine-command-  
30 information-word-length instructions cause controller, 20, to  
determine the number of signal words in the command  
information of said second message by adding H+X+L to said y-  
bits information of MMS-L and dividing the resulting sum by  
the number of bits in one signal word. Then said evaluate-  
35 end-condition instructions cause controller, 20, to place a

149

"0" at particular SPAM-Flag-@20 register memory if said command information fills a whole number of signal words exactly and "1" at said memory if it does not. And said calculate-number-of-words-to-transfer instructions cause  
5 controller, 20, to determine a particular number of signal words to transfer and place information of said number at particular working-@20 register memory.

Then said decrypt-a-00-header-message instructions cause controller, 20, to transmit to controller, 12, a  
10 particular transfer-decrypted-message instruction and particular decryption mark information of key J that identifies J as the decryption key.

Receiving said instruction and information causes controller, 12, to execute particular preprogrammed transfer-  
15 and-meter instructions then record said mark of key J at particular decryption-mark-@12 register memory.

Next said decrypt-a-00-header-message instructions cause controller, 20, to cause buffer/comparator, 8, to transfer to decryptor, 10, a quantity of signal words of said  
20 binary information of the second message which quantity is the number at said working-@20 register memory.

Buffer/comparator, 8, responds by transferring to decryptor, 10, binary information that begins at the first bit at said particular received signal location and transfers  
25 said information, signal word by signal word, until it has transferred said quantity of signal words.

Decryptor, 10, commences receiving said information, decrypting it using said key J information and transferring it to controller, 12, as quickly as controller, 12, accepts  
30 it. The process of decryption proceeds in a particular fashion. Said decrypt-a-00-header-message instructions cause controller, 20, to cause decryptor, 10, to transfer the first H bits without decrypting or altering said bits in any  
fashion, to decrypt and transfer the next X bits, to transfer the next L bits without decrypting or altering said bits, to  
35

150

decrypt and transfer the next MMS-L bits, and finally, to transfer any bits remaining after the last of said MMS-L bits without decrypting or altering said bits. In this fashion, the cadence information in said message, which is not  
5 encrypted, is transferred by decryptor, 10, to controller, 12, without alteration.

Under control of said transfer-and-meter instructions, controller, 12, commences receiving decrypted information of the second message from decryptor, 10. Having been  
10 decrypted, said information is identical to the binary information of the second message of example #1 (except that the meter-monitor information contains the aforementioned meter instruction information that is not in example #1 and the length token information of the meter-monitor format  
15 field reflects the presence of said instruction information).

Automatically controller, 12, processes said information of the second message of example #2 as a SPAM command. Receiving the header and execution segment causes controller, 12, to determine that said message is addressed  
20 to URS microcomputers, 205, and to transfer said message accordingly. Automatically, controller, 12, selects the first H converted bits and records said bits at particular SPAM-header-@12 register memory then selects the next X bits and records said bits at particular SPAM-exec-@12 register  
25 memory. Then, automatically, by comparing the information at said SPAM-exec memory with preprogrammed controlled-function-invoking-@12 information, controller, 12, determines that said information at memory matches preprogrammed transfer-this-message-to-205-@12 information. Automatically,  
30 controller, 12, executes preprogrammed transfer-to-205-@12 instructions; activates the output port that outputs to SPAM-controller, 205C; then commences transferring information of said decrypted information of the second message under control of said transfer-and-meter instructions commencing  
35 with the first of said H bits and transferring information,

151

signal word by signal word, in the order in which it is received from decryptor, 10. In addition, controller, 12, is preprogrammed with all instructions and information necessary for processing the length-token and determining the length of the meter-monitor segment of said second message, does so, and records at particular SPAM-meter register memory the first L plus MMS-L bits of said decrypted information immediately after the last of said X bits which is the information of the meter-monitor segment of said message.

When buffer/comparator, 8, completes transferring to decryptor, 10, the quantity of signal words that is the number at said working-@20 register memory, said decrypt-a-00-header-message instructions cause controller, 20, to execute said evaluate-padding-bits-? instructions, determine which signal word is the last word of the second message of example #2, and ensure that said word is transferred to decryptor, 10. Following the transfer of said word, controller, 20, causes decryptor, 10, to transmit particular decryption-complete information to controller, 20, when decryptor, 10, completes the transfer to controller, 12, of said word following its decryption.

Receiving said word at controller, 12, causes controller, 12, to transfer said word to SPAM-controller, 205C, and in so doing, complete the transfer of the decrypted information of said second message.

At microcomputer, 205, (and at the URS microcomputers, 205, at other stations where the second message of example #2 is decrypted) in the fashion described in example #1, said information, which is the unencrypted binary information of the second combining synch command, executes "GRAPHICS ON" causing microcomputer, 205, to combine the programming of Fig. 1A and of Fig. 1B and transmit said combined programming to monitor, 202M, where Fig. 1C is displayed.

(Meanwhile, no second combining synch command reaches the URS microcomputers, 205, at those subscriber stations

/52

whose URS signal processors, 200, are not preprogrammed with information of decryption key J because all received information of the second message of example #2 has been discarded. No combining occurs at said microcomputers, 205.  
5 And at the time when Fig. 1C is displayed at subscriber stations preprogrammed with said key J, the monitors, 202M, of said subscriber stations display Fig. 1B.)

Then receiving said decryption-complete information from decryptor, 10, causes controller, 20, to cause  
10 buffer/comparator, 8, to discard any information of said second message that may remain at buffer/comparator, 8, and commence processing in the conventional fashion; to cause decryptor, 10, to discard said key information of decryption key J and any information of said second message that may  
15 remain at decryptor, 10; to transmit to controller, 12, a preprogrammed complete-transfer-phase instruction; and, itself, to commence processing in the conventional fashion.

Receiving said complete-transfer-phase instruction causes controller, 12, to cease transferring information,  
20 under control of said transfer-and-meter instructions, to deactivate all output ports, and to commence executing the meter instructions of said transfer-and-meter instructions. Said meter instructions cause controller, 12, to compare the information at said SPAM-header-@12 memory with particular  
25 collect-meter-info information and determine that said H bits match particular "00" information. (In other words, said SPAM command information contains meter-monitor information.) Said match causes controller, 12, automatically to transfer to buffer/comparator, 14, particular header identification  
30 information that identifies controller, 12, as the source of said transfer the information recorded at said SPAM-meter memory then the information recorded at said decryption-mark-@12 register memory, which information is the decryption mark of key J. (Hereinafter, said meter information generated by  
35 the second combining synch command in example #2 is called

/53

the "2nd meter information (#2).") Following said transferring, controller, 12, automatically deletes from register memory all information of said second message and commences processing in the conventional fashion.

5       Receiving the 2nd meter information (#2) causes buffer/comparator, 14, automatically to execute a meter sequence that is fully automatic and for which all apparatus are preprogrammed and have capacity to perform.

Receiving said information causes buffer/comparator,  
10 14, to compare a particular portion of the meter-monitor format field of said 2nd meter information (#2) to particular distinguishing comparison information that identifies meter-monitor format fields that denote the presence of meter instruction fields. A match results which causes  
15 buffer/comparator, 14, to select information of bits at particular predetermined locations (which bits contain the information of the meter instruction field of said 2nd meter information (#2)) and compare said selected information to preprogrammed metering-instruction-comparison information and  
20 to determine that said field matches particular increment-by-one information that instructs buffer/comparator, 14, to add one incrementally to each meter record maintained at buffer/comparator, 14, that is associated with decryption key information that matches the decryption mark of the instance  
25 of meter information being processed. Accordingly, buffer/comparator, 14, compares the decryption mark of said 2nd meter information (#2) with preprogrammed decryption-key-comparison information. Said comparing results in more than one match, and buffer/comparator, 14, increments by one the  
30 meter record associated with each particular decryption-key-comparison datum that matches the decryption mark of said 2nd meter information (#2). Because the information of said meter instruction field instructs signal processor, 200, only to perform said incrementing, upon completing the last step  
35 of incrementing or comparing, automatically

154

buffer/comparator, 14, discards all information of said 2nd meter information (#2) except the incremented record information and commences processing in the conventional fashion.

5           Thus, not only does the second message of example #2 cause the combining of Fig. 1A and Fig. 1B and the display of Fig. 1C only at selected subscriber stations that are preprogrammed with decryption key J, it also causes the retaining of meter information associated with its own  
10 decryption at said selected stations.

Subsequently, decoder, 203, receives the third message of the "Wall Street Week" program which conveys the third combining synch command.

In example #2, all signal processing apparatus process  
15 the third combining synch command precisely as in the first example. Said command reaches all URS microcomputers, 205, and causes each to execute the aforementioned "GRAPHICS OFF" command. But only at those selected ones of said URS microcomputers, 205, that are preprogrammed with decryption  
20 key J does the third combining synch command actually cause combining to cease. At all other URS microcomputers, 205, executing "GRAPHICS OFF" has no effect because each of said other URS microcomputers, 205, is already in "Graphics Off" mode when said "GRAPHICS OFF" is executed. Because the  
25 aforementioned particular ones among said control invoking instructions that preceded the first message of the "Wall Street Week" program caused all URS microcomputers, 205, to set their PC-MicroKey 1300s to the "Graphics Off" mode and because no information of the second combining synch command  
30 reached said other microcomputers, 205, and executed "GRAPHICS ON", the PC-MicroKey 1300 of each of said other URS microcomputers, 205, is in "Graphics Off" mode when the third message of example #2 is transmitted.

Thus in example #2, not only does the second combining  
35 synch command cause the combining and the display of Fig. 1C

155

only at selected subscriber stations and the retaining of meter information at (and only at) said stations, it also causes selective processing--for example, the selecting of information of decryption key J at selected stations--that enables the third combining synch command to have effect only at selected stations without any selective processing of said third command. Placing particular so-called "soft switches," one of which exists at each subscriber station, all into one given original position, "off" or "on", then transmitting a command that is processed selectively at selected stations and places said switches at said stations into the opposite position, "on" of "off", makes it possible to transmit a subsequent command that returns said switches at said selected stations (and only said switches) to said original position without any additional selective processing.

Significant advantages of simplicity and speed are achieved by devising signal processing apparatus and methods that minimize the need for selective processing. With regard to said third combining synch command, for example, no step of decrypting is required to affect only those stations that are preprogrammed with decryption key J. Accordingly, no possibility exists that an error in decrypting may occur at one or more of said stations, causing the combining of video RAM information and received video information, at said one or more, not to cease at the proper time and to continue beyond said time (until such time as some subsequent command may execute "GRAPHICS OFF" or clear information from said video RAM at said stations). Because no time is required for decrypting, no possibility exists that some station may take longer (or shorter) than proper to perform decrypting causing the image of Fig. 1A to be displayed at some monitor, 202M, longer (or shorter) than proper. Perhaps most important, because no time is required for selective processing of said third command, the time interval that separates the time of embedding said third command at said remote station that

156

originates the "Wall Street Week" program and the time of ceasing caused by said command at URS microcomputers, 205, can be the shortest possible interval. Making it possible for said time interval to be the shortest possible interval  
5 minimizes the chance that an error may occur in the timing of the embedding of said third command at said remote station causing all URS microcomputers, 205, to cease combining at a time that is other than the proper time.

10 THE PREFERRED CONFIGURATION OF CONTROLLER, 39, AND SPAM-CONTROLLER, 205C.

Heretofore, this specification has treated the controller of decoder, 203, (which is controller, 39) and the SPAM input controller of microcomputer, 205, (which is SPAM-  
15 controller, 205C) as separate controllers. This treatment has served to show how SPAM messages are transferred from one controller to another, at any given subscriber station.

But, in the preferred embodiment, the controller of the decoder that detects the SPAM signals of a combined  
20 medium transmission, at any given subscriber station, and the controller that executes the information of said signals at the microcomputer that combines the local and broadcast programming, at said station, are one and the same. More precisely, controller, 39, of decoder, 203, and SPAM-  
25 controller, 205C, are one and the same (and are called, hereinafter, "controller, 39"). Thus the preferred embodiment of controller, 39, is configured and preprogrammed not only to control the detecting, correcting, converting, and executing of controlled functions at decoder, 203, but  
30 also to input to and execute at microcomputer, 205, the information of any given detected SPAM message that is addressed to URS microcomputers, 205.

Fig. 3A shows one such preferred controller, 39.

One aspect of the preferred embodiment of controller,  
35 39, is a series of buffers and processors at which forward

157

error correction, protocol conversion, and the invoking of controlled functions take place in series. Buffer, 39A, and processor, 39B, are the first buffer and processor of the series and perform the forward error correcting functions of controller, 39. Buffer, 39C, and processor, 39D, are the second buffer and processor and perform protocol conversion functions. Buffer, 39E, and control processor, 39J, are the third buffer and processor. All controlled functions invoked at controller, 39, by received SPAM signals are invoked at control processor, 39J.

Performing forward error correction and protocol conversion and invoking the controlled functions at a series of processors, in this fashion, rather than sequentially at one processor has significant advantages as regards speed. Inputting the information of each SPAM signal word to three processors does take longer than inputting said information to just one processor. But this is more than offset by the fact that having three processors rather than just one enables controller, 39, to process the information of three signal words simultaneously. Control processor, 39J, can invoke and process the controlled function of a first signal word while processor, 39D, converts the information of a second signal word and processor, 39B, corrects the information of a third signal word.

A second aspect of the preferred embodiment of controller, 39, is a matrix switch, 39I, that operates under control of control processor, 39J, and can transfer information of received SPAM signals from buffer, 39E, directly to addressed apparatus. Transferring said information in this fashion rather than through control processor, 39J, has the advantage of freeing control processor, 39J, to perform other functions while said information is transferred.

As Fig. 3A shows, each processor, 39B, 39D, and 39J, has associated RAM and ROM and, hence, constitutes a

158

programmable controller in its own right. Each processor, 39B, 39D, and 39J, controls its associated buffer, 39A, 39C, and 39E respectively. Each buffer, 39A, 39C, and 39E, is a conventional buffer that receives, buffers, and transfers  
5 binary information in fashions well known in the art. Each buffer, 39A and 39C, transfers its received and buffered information to its associated processor, 39B and 39D respectively, for processing. Buffer, 39E, transfers its received and buffered information, via EOFs Valve, 39F, to  
10 matrix switch, 39I.

The preferred embodiment of controller, 39, also has a buffer, 39G, that is a conventional buffer with means for receiving information from other inputs external to decoder, 203. Among said inputs is, in particular, an input from  
15 controller, 12, of signal processor, 200 (which input performs the functions of the input from controller, 12, to SPAM-controller, 205C, shown in Fig. 3). Buffer, 39G, outputs its received and buffered information, via EOFs Valve, 39H, to matrix switch, 39I. Buffer, 39G, is  
20 configured, in a fashion well known in the art, with capacity to identify to control processor, 39J, which input is the source of any given instance of information received and buffered at buffer, 39G, and capacity to output selectively, under control of control processor, 39J, any given instance  
25 of received information.

EOFs Valves, 39F and 39H, are EOFs valves of the type described above and transfer the buffered information of buffers, 39E and 39G respectively, to matrix switch, 39I. Said valves operate under control of control processor, 39J,  
30 and monitor all information, so transferred, continuously for end of file signals in the fashion described above.

Matrix switch, 39I, is a conventional digital matrix switch, well known in the art of telephone communication switching, that is configured for the small number of inputs  
35 and outputs required at controller, 39. Matrix switch, 39I,

159

operates under control of control processor, 39J, and has capacity to receive SPAM signal information from a multiplicity of inputs, including EOFs Valves, 39E and 39F, and from control processor, 39J, and to transfer said  
5 information to a multiplicity of outputs, including control processor, 39J; the CPU of microcomputer, 205; buffer/comparator, 8, of signal processor, 200; buffer/comparator, 14, of signal processor, 200; and other outputs. Among such other outputs is one or more  
10 (hereinafter called, "null outputs") with capacity for accepting binary information and merely recording said information at particular memory associated with matrix switch, 39I, thereby overwriting and obliterating information previously recorded at said memory. The purpose of such a  
15 null output is to provide means whereby said switch can automatically cause information of any selected SPAM message to be discarded rather than transferred to addressed apparatus. (Other examples of other outputs are cited below.) Matrix switch, 39I, also has capacity to receive  
20 control information from control processor, 39J, and transfer said information to the CPU and/or the PC-MicroKey 1300 system of microcomputer, 205, and to receive control information from the CPU and/or the PC-MicroKey 1300 system of microcomputer, 205, and transfer said information to  
25 control processor, 39J. Matrix switch, 39I, transfers information in such a way that information inputted at any given input is transferred to a selected one or ones of said outputs without modification, and a multiplicity of information transfers can take place simultaneously.

30 Control processor, 39J, has capacity for computing information and processing all control information necessary for controlling all apparatus of decoder, 203 (or such other decoder as the controller of a given control processor, 39J, may be installed in). In keeping with the function of  
35 control processor, 39J, as the processor at which all

160

controlled functions of controller, 39, are invoked, all  
aforementioned particular register memories of controller,  
39, are located at control processor, 39J. The register  
memories of control processor, 39J, include (but are not  
5 limited to) particular SPAM-input-signal register memory  
whose length in bit locations is sufficient to contain the  
longest possible instance of SPAM command information with  
associated padding bits; the aforementioned SPAM-header and  
SPAM-exec register memories; particular SPAM-Flag-monitor-  
10 info, SPAM-Flag-at-secondary-control-level, SPAM-Flag-  
executing-secondary-command, SPAM-Flag-secondary-level-  
incomplete, SPAM-Flag-primary-level-2nd-step-incomplete,  
SPAM-Flag-primary-level-3rd-step-incomplete, SPAM-Flag-  
secondary-level-2nd-step-incomplete, SPAM-Flag-secondary-  
15 level-3rd-step-incomplete, SPAM-Flag-first-condition-failed,  
SPAM-Flag-second-condition-failed, SPAM-Flag-do-not-meter,  
and SPAM-Flag-working register memories each of which are one  
bit location in length; the aforementioned SPAM-length-info,  
SPAM-mm-format, SPAM-first-precondition, SPAM-second-  
20 precondition, SPAM-last-01-header-exec register memories;  
particular SPAM-decryption-mark, SPAM-primary-input-source,  
SPAM-secondary-input-source, SPAM-next-primary-instruction-  
address, SPAM-next-secondary-instruction-address, SPAM-  
executing-secondary-command, SPAM-last-secondary-01-header-  
25 exec, SPAM-address-of-next-instruction-upon-primary-  
interrupt, and SPAM-address-of-next-instruction-upon-  
secondary-interrupt register memories whose functions are  
described below; and a plurality of working register memories  
that include first-working and second-working register  
30 memories. (With the exception of the memories whose names  
include the word "working," all the aforementioned register  
memories are dedicated strictly to the functions described  
below and are not used for any other functions.) All  
preprogrammed information associated with the identification  
35 and execution of controlled functions and the aforementioned

161

conventional instructions that control controller, 39, are preprogrammed at the RAM and/or ROM associated with control processor, 39J. Examples of said preprogrammed information include relevant information of the aforementioned

5 controlled-function-invoking information, process-length-token instructions, and execute-conditional-overlay-at-205 information (that is part of the aforementioned controlled-function-invoking-@205 information).

Besides being the processor at which all controlled

10 functions of controller, 39, are invoked, control processor, 39J, is the processor that controls all controlled apparatus of decoder, 203, (except for a decryptor, 39K, described more fully below) and controls all apparatus described above as being controlled by SPAM-controller, 205C. Control

15 processor, 39J, controls not only buffers, 39E and 39G, valves, 39F and 39H, and switch, 39I, but also processors, 39B and 39D, as well as all other apparatus of decoder, 203, controlled by controller, 39. Control processor, 39J, has

20 all required transmission capacity for transmitting control instructions to and receiving control information from all such controlled apparatus. In addition, control processor, 39J, controls the CPU and the PC-MicroKey 1300 system of microcomputer, 205, in certain SPAM functions and has

25 capacity, via matrix switch, 39I, to transmit control information to and receive control information from said CPU and said PC-MicroKey 1300 system. In certain SPAM functions, controller, 20, of signal processor, 200, controls control processor, 39J, and as Fig. 3A shows, control processor,

30 39J, has means for communicating control information directly with said controller, 20. The RAM and/or ROM associated with control processor, 39J, are preprogrammed with all information necessary for controlling all such controlled apparatus.

As Fig. 3A shows, the preferred embodiment of

35 controller, 39, also has a decryptor, 39K. Said decryptor,

162

39K, is a conventional decryptor that is identical to decryptor, 10, of signal processor, 200. Decryptor, 39K, receives inputted information from matrix switch, 39I; outputs its information to buffer, 39H; has means for communicating control information directly with controller, 20, of signal processor, 200; and is controlled by said controller, 20. Decryptor, 39K, is preprogrammed with relevant SPAM information (e.g., information of H, X, and L) and has capacity for processing SPAM message information in fashions described more fully below.

In the preferred embodiment, to maximize the speed of information transmission, all apparatus of controller, 39, are located physically on one so-called silicon microchip and communicate with one another, in fashions well known in the art, by means of the circuits of said chip. All apparatus of said chip function, in a fashion well known in the art, at the same clock speed. Said speed may be the speed of the control clock of microcomputer, 205, communicated to controller, 39, in an appropriate fashion, well known in the art. Or said speed may be the control clock speed of signal processor, 200.

Examples #3 and #4 of the combining of the "Wall Street Week" program described above, which relate elaborations of examples #1 and #2, illustrate in detail the operation of the preferred embodiment of controller, 39.

#### OPERATING S. P. SYSTEMS ... EXAMPLE #3 (FIRST WORD)

Example #3 differs from example #1 in just two respects.

First, example #3 focuses on selected subscriber stations where signal processing apparatus and methods are used to collect monitor information for so-called "program ratings" (such as so-called "Nielsen ratings") that estimate the sizes of television (or radio) program audiences. In the present invention, subscriber stations can be preprogrammed

163

to process and record monitor information of SPAM commands and transfer said information to one or more remote data collection stations where computers process the monitor information to generate such ratings. In example #3, all apparatus of the subscriber station of Fig. 3 are so preprogrammed, and buffer/comparator, 14, of signal processor, 200, operates, in fashions described more fully below, under control of the aforementioned on-board controller, 14A.

Second, the controller, 39, of example #3 is the preferred embodiment of controller, 39, and replaces the controller, 39, and SPAM-controller, 205C, of example #1. Insofar as messages addressed to URS microcomputers, 205, are concerned, the preferred embodiment of controller, 39, is preprogrammed to perform the controlled functions of the SPAM-controller, 205C, of example #1. Thus the preprogrammed information at the RAM and/or ROM associated with control processor, 39J, includes, for example, the execute-at-205, execute-conditional-overlay-at-205, and cease-overlay information and the load-run-and-code, conditional-overlay-at-205, and cease-overlaying-at-205 instructions preprogrammed at SPAM-controller, 205C, in example #1.

In all other respects example #3 is identical to example #1.

Example #3 begins, like example #1, with divider, 4, transferring the embedded information of the first message to decoder, 203. In the same fashion that applied in example #1, receiving said embedded information at decoder, 203, causes the binary information of said first message to be received, with error correcting information, at decoder, 203, and detected at digital detector, 34. Detector, 34, inputs the detected information to controller, 39, at buffer, 39A.

The first step of processing at controller, 39, takes place at processor, 39B, where error correction occurs. As said detected information is inputted, buffer, 39A, receives,

164

5 buffers, and transfers said information, signal word by signal word, an to processor, 39B, in a fashion well in the art. Processor, 39B, receives each word, in turn, with its associated error correcting information and uses the error  
5 correcting information, in its forward error correcting fashion, to check the binary information of said word and correct the information of said word, as required, then transfers the correct information of said word to buffer, 39C, and discards said error correcting information.

10 The second step of processing is protocol conversion and takes place at processor, 39D. Buffer, 39C, receives and buffers the corrected information of each word, in turn, and transfers said information to processor, 39D. As processor, 39D, receives said information, in its protocol conversion  
15 fashion, processor, 39B, converts the corrected binary information of each word into converted information that all appropriate subscriber station apparatus can receive and process and transfers the converted information of each word to buffer, 39E.

20 As buffer, 39E, receives the corrected information of each word, buffer, 39E, buffers and transfers said information to EOFs valve, 39F, as quickly as said valve, 39F, is prepared to receive said information. EOFs valve, 39F, processes said information, in its end of file signal  
25 detecting fashion described above, to detect information of an end of file signal and outputs said information to matrix switch, 39I, as quickly as the apparatus to which said switch, 39I, transfers said information is prepared to receive said information. As matrix switch, 39I, receives  
30 the converted information of each word, said switch, 39I, transfers said information to a selected output port of said switch, 39I. Said selected port is the particular port to which control processor, 39J, causes said switch, 39I, to transfer said information.

35 At the outset of example #3, matrix switch, 39I, is

165

configured to input the output of EOFs Valve, 39F, to control processor, 39J, and control processor, 39J, awaits header information.

When EOFs valve, 39F, commences transferring the SPAM  
5 information of the first message of example #3, control processor, 39J, executes a first step of receiving SPAM message information and receives the header information in said first message. Control processor, 39J, accepts, receives in turn, and records in sequence at particular SPAM-  
10 input-signal register memory a particular first quantity of said words. Said first quantity is the smallest number of signal words that can contain one instance of header information (that is, H bits). In the simplest preferred embodiment where a SPAM header is two bits long and signal  
15 words are eight-bit bytes, said first quantity is one. Then, automatically, control processor, 39J, ceases accepting SPAM signal information transferred from EOFs valve, 39F, and said valve, 39F, commences holding the next processed signal word of said first message until control processor, 39J, becomes  
20 prepared, once again, to accept and receive SPAM signal information.

Then control processor, 39J, processes said header information. Automatically, control processor, 39J, selects information of the first H bits at said SPAM-input-signal  
25 memory and records said information of H bits at said SPAM-header memory then compares the information at said SPAM-header memory to the aforementioned ll-header-invoking information that is "ll". No match results.

Because control processor, 39J, and the RAM and ROM  
30 associated with said processor, 39J, are preprogrammed to process the monitor information of SPAM commands to provide viewership data for remote computer processing, not resulting in a match with said ll-header-invoking information causes control processor, 39J, to execute particular  
35 preprogrammed

166

evaluate-message-content instructions before receiving and processing the execution segment information in said first message. Automatically, said instructions cause control processor, 39J, to compare the information at said SPAM-  
5 header memory with preprogrammed invoke-monitor-processing information. A match results with particular "01" information. Said match signifies the presence of meter-monitor information in said first message and causes control processor, 39J, to enter "0" at particular SPAM-Flag-monitor-  
10 info register memory that is normally "1".

Then automatically control processor, 39J, executes a second step of receiving SPAM signal information and receives the execution segment information in said first message. Automatically, control processor, 39J, commences accepting  
15 and EOFs valve, 39F, commences transferring additional SPAM signal words. Automatically, control processor, 39J, receives and records said words in sequence at said SPAM-input-signal memory immediately following the last of said first quantity of signal words until the total quantity of  
20 SPAM signal words recorded at said memory equals a particular second quantity. Said second quantity is the smallest number of signal words that can contain one instance of header and execution segment information (that is, H+X bits). (If H+X bits can be contained in one signal word, said second  
25 quantity equals said first quantity, and control processor, 39J, records no additional SPAM signal words in the course of said second step of receiving SPAM signal information.) Automatically, control processor, 39J, ceases accepting SPAM signal information transferred from EOFs valve, 39F.

30 Then control processor, 39J, processes said execution segment information. Automatically, control processor, 39J, selects information of the first X bits of information at said SPAM-input-signal memory immediately after the first H bits, records said information of X bits at said SPAM-exec  
35 memory, and compares the information at said SPAM-exec memory

167

with controlled-function-invoking information that is preprogrammed at the RAM and/or ROM associated with said processor, 39J. A match results with the aforementioned execute-at-205 information that is identical to the execute-at-205 information preprogrammed at SPAM-controller, 205C, of example #1. Said match causes control processor, 39J, to execute the aforementioned load-run-and-code instructions. Said instructions cause control processor, 39J, to place "0" at the aforementioned SPAM-Flag-primary-level-2nd-step-incomplete register memory and, separately, at SPAM-Flag-primary-level-3rd-step-incomplete register memory, which information signifies that specific load-run-and-code controlled functions have not been completed, and to place information of a particular reentry-address at the aforementioned SPAM-address-of-next-instruction-upon-primary-interrupt register memory which reentry-address specifies the location of the next decrypt-process-and-meter-current-message instruction to be executed when interrupt information of a detected end of file signal is received by control processor, 39J, from EOFs valve, 39F. Then said instructions cause control processor, 39J, to compare the information at said SPAM-header memory with preprogrammed header-identification information and determine a match with particular preprogrammed "01" information.

Under control of said instructions, said match causes control processor, 39J, automatically to execute a third step of receiving SPAM signal information and receive the length token information in said first message. Automatically, control processor, 39J, commences accepting and EOFs valve, 39F, commences transferring additional SPAM signal words. Automatically, control processor, 39J, receives and records said words in sequence at said SPAM-input-signal memory immediately following the last of said second quantity of signal words until the total quantity of SPAM signal words recorded at said memory equals a particular third quantity.

168

Said third quantity is the smallest number of signal words that can contain one instance of header, execution segment, and length token information (that is,  $H+X+L$  bits). Then, automatically, control processor, 39J, ceases accepting SPAM  
5 signal information transferred from EOFs valve, 39F.

Automatically, control processor, 39J, processes said length token information. The RAM and ROM associated with control processor, 39J, are preprogrammed with all information necessary to determine the length of SPAM  
10 commands including information of H, X, L, and  $H+X$ ; process-length-token, determine-command-information-word-length, evaluate-end-condition, calculate-number-of-words-to-transfer, evaluate-padding-bits-? instructions; and token-comparison, W-token, X-token, Y-token, Z-token, w-bits, x-  
15 bits, y-bits, z-bits, A-format, B-format, C-format, and D-format information. Said preprogrammed instructions and information cause control processor, 39J, to determine the number of signal words of command information in said first message in precisely the same fashion that controller, 39,  
20 determined the number of signal words of command information in the second message in example #2. Automatically, control processor, 39J, selects information of the first L bits of information at said SPAM-input-signal memory immediately after the first  $H+X$  bits and records said information of L  
25 bits at SPAM-length-info memory. Said L bits are the length token of said message. Automatically control processor, 39J, determines that the information at said SPAM-length-info memory matches said W-token information, selects said w-bits information, and processes said information as the numeric  
30 value of  $MMS-L$ . Automatically, control processor, 39J, determines the number of signal words in the command information of said second message by adding  $H+X+L$  to said w-bits information of  $MMS-L$  and dividing the resulting sum by the number of bits in one signal word. Automatically control  
35 processor, 39J, places a "0" at particular SPAM-Flag-working

169

register memory if said command information fills a whole number of signal words exactly and "1" at said memory if it does not. Automatically, control processor, 39J, then determines a particular number of signal words to transfer 5 and place information of said number at particular working register memory.

Next said load-run-and-code instructions cause control processor, 39J, to execute a fourth step of receiving SPAM signal information and commence receiving all remaining 10 command information and padding bits in said first message. Automatically, control processor, 39J, commences accepting and EOFs valve, 39F, commences transferring additional SPAM signal words. Automatically, control processor, 39J, receives and records said words in sequence at said SPAM- 15 input-signal memory immediately following the last of said third quantity of signal words until the total quantity of SPAM signal words recorded at said memory equals a particular fourth quantity. Said fourth quantity is the number at said working register memory. Then, automatically, control 20 processor, 39J, compares the information at said SPAM-Flag-working register memory to particular information that is "0".

Not resulting in a match means that EOFs valve, 39F, has transferred and control processor, 39J, has recorded all 25 command information of said first message together with any associated padding bits. Accordingly, not resulting in a match causes control processor, 39J, to cease accepting SPAM signal information from EOFs valve, 39F.

On the other hand, resulting in a match means that one 30 full signal word of padding bits may follow the last signal word of said message that contains command information and that said last word must be evaluated to ascertain whether it contains MOVE bit information. Accordingly, under control of said preprogrammed instructions, resulting in a match causes 35 control processor, 39J, to receive one additional signal word

170

from EOFs valve, 39F, to compare said word to particular preprogrammed information of one EOFs WORD, and to record said word at said SPAM-input-signal memory immediately following the last of said fourth quantity of signal words.

5 Said word is the last signal word of said message that contains command information. If said word matches said information of one EOFs WORD, one full signal word of padding bits follows said word, and said preprogrammed instructions cause control processor, 39J, to receive one more signal word

10 from EOFs valve, 39F, and to record said word at said SPAM-input-signal memory immediately following said last signal word that contains command information. Then, whether or not a match has occurred with said information of one EOFs WORD, said preprogrammed instructions cause control processor, 39J,

15 to cease accepting SPAM signal information from EOFs valve, 39F.

By receiving all command information and padding bits in said first message in the course of said four steps of receiving SPAM signal information, control processor, 39J,

20 causes EOFs valve, 39F, to transfer every signal word in said first message prior to the first word of the information segment of said first message. Accordingly, the next signal word transferred by said valve, 39F, is the first word of said information segment, which is the first word of the

25 program instruction set of the "Wall Street Week" combining.

Then said load-run-and-code instructions cause control processor, 39J, to commence loading information at the main RAM of microcomputer, 205. Automatically, under control of said instructions, control processor, 39J, causes matrix

30 switch, 39I, to cease transferring information from EOFs valve, 39F, to control processor, 39J, and to commence transferring information from control processor, 39J, to the CPU of microcomputer, 205; transmits an instruction to said CPU that causes said CPU to commence receiving information

35 from matrix switch, 39I, and loading said information at

171

particular main RAM in a fashion well known in the art; and causes matrix switch, 39I, to commence transferring information from EOFs valve, 39F, to said CPU.

Automatically, microcomputer, 205, commences receiving the  
5 information of the program instruction set in said first message, beginning with the first signal word of said set, and loads said information at particular main RAM.

Then, while EOFs valve, 39F, processes the information of the information segment of said first message to detect  
10 the end of file signal and while microcomputer, 205, loads the information of said program instruction set at RAM, said load-run-and-code instructions cause control processor, 39J, to commence executing the code portion of said instructions. The instructions of said portion cause control processor,  
15 39J, to compare the information at said SPAM-header memory to particular load-run-and-code-header information that is "01". A match results (which indicates that said first message contains meter-monitor information). Control processor, 39J is preprogrammed with evaluate-meter-monitor-format, process-  
20 this-specific-format, and locate-program-unit instructions and with format-specification information and offset-address information, and said match control processor, 39J, to locate the "program unit identification code" information in the information at said SPAM-input-signal memory and record  
25 information of said "code" information at SPAM-first-precondition register memory in the same fashion that SPAM-controller, 205C, performed these functions in example #1.

To locate said "code" information, said code portion instructions cause control processor, 39J, to execute said  
30 evaluate-meter-monitor-format instructions. Said instructions cause control processor, 39J, to select information of bits at particular predetermined locations at said SPAM-input-signal memory and record said information at SPAM-mm-format register memory. Said bits are the bits of  
35 the meter-monitor format field in said first message. Then

172

said instructions cause control processor, 39J, to compare the information at said SPAM-mm-format memory with said format-specification information, determine a match with particular A-format information that invokes particular  
5 process-A-format instructions, and execute said instructions. Said instructions cause control processor, 39J, to place a particular A-offset-address number at said SPAM-mm-format memory (thereby overwriting and obliterating the information previously at said memory) which number specifies the  
10 address/location at the RAM associated with control processor, 39J, of the first bit of information that identifies the specific format of the meter-monitor segment in said first message.

Then said code portion instructions cause control  
15 processor, 39J, to execute the aforementioned locate-program-unit instructions. Said instructions cause controller, 39J, to add a particular preprogrammed program-unit-field-start-datum-location number to information of said A-offset-address number and record the resulting first sum then add a  
20 particular preprogrammed program-unit-field-length-datum-location number to information of said A-offset-address number and record the resulting second sum. Next said instructions cause control processor, 39J, to select preprogrammed binary information of a particular  
25 preprogrammed datum-cell-length number of contiguous bit locations that begin at said first sum number of bit locations after a particular predetermined first-bit location at said RAM and place said binary information at first-working register memory and to select preprogrammed binary  
30 information of said datum-cell-length number of contiguous bit locations that begin at said second sum number of locations after said first-bit location and place said binary information at second-working register memory. In so doing, control processor, 39J, places at said first-working memory  
35 information of the bit distance from the first bit location

173

of said SPAM-input-signal memory to the first bit location of said program unit field and places at said second-working memory information of the bit location length of said program unit field. Automatically, control processor, 39J, selects  
5 binary information of the second-working memory information number of contiguous bit locations at said SPAM-input-signal memory that begin at the first-working memory information number of bit locations after the first bit location at said memory. Automatically, control processor, 39J, places said  
10 binary information at said first-working memory. In so doing, control processor, 39J, selects information of the unique "program unit identification code" that identifies said "Wall Street Week" program.

Then said code portion instructions cause control  
15 processor, 39J, to place at the aforementioned SPAM-first-precondition memory information of said information at first working memory. In so doing, control processor, 39J, places said "code" at said memory. Then the final instructions of said portion cause control processor, 39J, place "1" at SPAM-  
20 Flag-primary-level-3rd-step-incomplete register memory (thereby overwriting and obliterating the "1" information at said memory), which "1" signifies the completion of the code step executed by said load-run-and-code instructions.

(At stations that are not preprogrammed to collect  
25 monitor information, each control processor, 39J, commences waiting for interrupt information of the end of file signal at the end of said first message from EOFs valve, 39F, when each completes the code portion of said load-run-and-code instructions.)

30 The station of Fig. 3 is preprogrammed to collect monitor information, and at any point where the control processor, 39J, of a station that is not so preprogrammed commences waiting, the control processor, 39J, of the station of Fig. 3 is preprogrammed automatically to execute  
35 particular preprogrammed collect-monitor-info instructions.

174

Said instructions cause control processor, 39J, of the station of Fig. 3 to compare the information at said SPAM-Flag-monitor-info memory with particular preprogrammed "0" information. A match results. Under control of said instructions, said match causes control processor, 39J, to cause matrix switch, 39I, to commence transferring information from control processor, 39J, to buffer/comparator, 14, of signal processor, 200, (while said switch is simultaneously transferring information from control processor, 39J, to the CPU of microcomputer, 205); to transfer to said buffer/comparator, 14, header information that identifies a transmission of monitor information then particular decoder-203 information that is the source mark of said decoder, 203, (which source mark is binary information that is preprogrammed at control processor, 39J) then all of the received binary information of said first message that is recorded at said SPAM-input-signal memory; then to cause matrix switch, 39I, to cease transferring information from control processor, 39J, to said buffer/comparator, 14. (Said received information is complete information of the first combining synch command, and said information transmitted to buffer/comparator, 14, is called, hereinafter, the "1st monitor information (#3).") Then control processor, 39J, enters "1" at said SPAM-Flag-monitor-info memory, signifying completion of the transfer of said 1st monitor information (#3); completes said collect-monitor-info instructions; and commences waiting for interrupt information of end of file signal, transmitted by control transmission means.

In due course, EOFs valve, 39F, receives the last signal word of the information segment of said first message, which is the last signal word of said program instruction 7set, and transfers said word, via matrix switch, 39I, to microcomputer, 205, which causes microcomputer, 205, to load said word at said RAM.

Then said valve, 39F, commences receiving information

175

of the eleven EOFS WORDs that constitute the end of file signal at the end of said first message. Receiving the first EOFS WORD of said eleven causes EOFS valve, 39F, to commence retaining information of said WORD, in the fashion described above, and to cease transferring information to microcomputer, 205. Accordingly, microcomputer, 205, ceases loading information at said RAM. Said valve, 39F, detects and retains information of the next nine EOFS WORDs in its end of file signal detection fashion. Then, receiving the eleventh and last EOFS WORD of said end of file signal causes EOFS valve, 39F, to increment the information at the EOFS WORD Counter of said valve, 39F, by one then determine that the information at said Counter matches the information at the EOFS Standard Length Location of said valve, 39F, which causes EOFS valve, 39F, to transmit EOFS-signal-detected information to control processor, 39J, as an interrupt signal then commence waiting for a control instruction from control processor, 39J.

Receiving an interrupt signal of EOFS-signal-detected information from an EOFS valve, 39F or 39H, while under control of any given set of preprogrammed controlled function instructions causes control processor, 39J, to execute a so-called "machine language jump" to a predesignated portion of said instructions, in a fashion well known in the art, and execute the instructions of said portion.

In the case of said load-run-and-code instructions, receiving an EOFS-signal-detected interrupt signal causes control processor, 39J, to jump to and execute the run portion of said instructions. Receiving the EOFS-signal-detected interrupt signal that the eleventh EOFS WORD of the end of file signal at the end of said first message causes EOFS valve, 39F, to transmit causes control processor, 39J, to jump to and execute instructions that begin with that particular one whose location is identified by the reentry-address information at the aforementioned SPAM-address-of-

176

next-instruction-upon-primary-interrupt register memory. Said instructions are the instructions of said run portion. Automatically, said instructions cause control processor, 39J, to cause matrix switch, 39I, to cease transferring  
5 information from EOFs valve, 39F, to the CPU of microcomputer, 205, and to commence transferring information from control processor, 39J, to said CPU; to transmit a control instruction to said CPU that causes microcomputer, 205, to cease loading information at said main RAM and  
10 execute the information so loaded as so-called "machine executable code" of one so-called "job"; then to transmit the aforementioned discard-and-wait instruction, via control transmission means, to EOFs valve, 39F. In so doing, control processor, 39J, completes the instructions of said run  
15 portion.

Receiving said discard-and-wait instruction causes EOFs valve, 39F, to set the information at said EOFs WORD Counter to "00000000", to transmit the aforementioned complete-and-waiting information to control processor, 39J,  
20 as a second interrupt signal, then to commence waiting for a further control instruction from control processor, 39J.

Automatically said load-run-and-code instructions cause control processor, 39J, to compare the information at said SPAM-Flag-primary-level-3rd-step-incomplete memory  
25 with particular preprogrammed "1" information. A match results which signifies that control processor, 39J, has already completed the code portion of said load-run-and-code instructions. Said match causes control processor, 39J, to complete said load-run-and-code instructions.

30 Having completed the controlled functions of said first message, automatically control processor, 39J, prepares to receive the next SPAM message. Automatically, control processor, 39J, determines, in a predetermined fashion, that EOFs valve, 39F, is the primary input to control processor,  
35 39J, of SPAM message information; causes matrix switch, 39I,

177

to commence transferring information from EOFS valve, 39F, to control processor, 39J; then compares the information at said SPAM-header memory to particular preprogrammed cause-retention-of-exec information that is "01". A match results which causes control processor, 39J, to place at the aforementioned SPAM-last-01-header-exec register memory information of the information at said SPAM-exec memory. Being preprogrammed to collect monitor information, control processor, 39J, automatically compares the information at said SPAM-Flag-monitor-info memory with particular preprogrammed "0" information. No match results which indicates that control processor, 39J, has completed collect-monitor-info instructions in respect to said first message. Then, automatically, control processor, 39J, causes all apparatus of control processor, 39J, to delete from memory all information of said first message except information at said SPAM-first-precondition and SPAM-last-01-header-exec memories. Finally, after receiving said complete-and-waiting information from EOFS valve, 39F, control processor, 39J, causes said valve, 39F, to commence processing inputted signal words, in its preprogrammed detecting fashion, and outputting information to matrix switch, 39I, and control processor, 39J, commences waiting to receive information of a subsequent SPAM header from said switch, 39I.

As described in "One Combined Medium" above, running the information of said program instruction set causes microcomputer, 205, (and URS microcomputers, 205, at other subscriber stations) to place appropriate Fig. 1A image information at particular video RAM. In addition, running said set also causes microcomputer, 205, after completing placing said image information at said RAM, to transfer particular number-of-overlay-completed information and instructions to control processor, 39J. Said information and instructions cause control processor, 39J, to place the number "00000001" at particular SPAM-second-precondition

178

register memory at control processor, 39J, signifying that said image information represents the first overlay of its associated video program.

Receiving said 1st monitor information (#3) causes  
5 buffer/comparator, 14, to compare the information, in said  
1st information, of the header information that identifies a  
transmission of monitor information to particular  
preprogrammed header-identification-@14 information. A match  
results with particular monitored-instruction-fulfilled-  
10 identification information which causes buffer/comparator,  
14, to input said 1st monitor information (#3) to onboard  
controller, 14A.

Receiving said 1st monitor information (#3) causes  
onboard controller, 14A, to record the source mark  
15 information in said 1st information at particular source-  
mark-@14A register memory; to record at particular SPAM-  
input-signal-@14A register memory all of the received binary  
information of said first message that was recorded at the  
aforementioned SPAM-input-signal memory of controller, 39J;  
20 and to execute particular preprogrammed process-monitor-info  
instructions. (Onboard controller, 14A, processes the 1st  
monitor information (#3) upon receipt, and this processing  
can occur simultaneously with the loading of the program  
instruction set of said first message at RAM at  
25 microcomputer, 205, while control processor, 39J, waits to  
receive an EOFs-signal-detected signal from EOFs valve, 39F.)  
Automatically, said instructions cause onboard controller,  
14A, to compare the information at said source-mark-@14A  
memory, in a predetermined fashion, with particular pre-  
30 entered source-identification mark information that onboard  
controller, 14A, retains in memory associated with its  
pre-entered signal records of monitor information. A match  
results with that particular decoder-203 source mark  
information that is associated with the aforementioned record  
35 of the prior programming displayed at monitor, 202M. Said

179

match causes onboard controller, 14A, to locate the instance of "program unit identification code" information in the information at said SPAM-input-signal-@14A register memory in precisely the same fashion that the code portion instructions 5 of the aforementioned load-run-and-code instructions caused controller, 39J, to locate "program unit identification code" information in information of said first message. (Onboard controller, 14A, is preprogrammed with all information necessary for locating and processing the information of all 10 the meter-monitor fields in any monitor information transmission such as said 1st monitor information (#3)--said preprogrammed information includes, for example, format-specification information, A-format information, and locate-program-unit instructions.) Automatically, said process- 15 monitor-info instructions cause onboard controller, 14A, in a predetermined fashion, to locate the instance of "program unit identification code" information in said record of the prior programming displayed at monitor, 202M, and to compare said first named instance of "program unit identification 20 code" information to said second named instance. No match results.

Not resulting in a match causes onboard controller, 14A, to cause signal processor, 200, to record said record of prior programming at recorder, 16. Automatically, 25 under control of said process-monitor-info instructions, onboard controller, transmits to controller, 20, a particular preprogrammed instruct-to-record instruction that causes controller, 20, to cause onboard controller, 14A, to transmit the monitor record of said prior programming to recorder, 16, 30 in a predetermined fashion and that causes controller, 20, to cause recorder, 16, to record said monitor record information in a predetermined fashion. (Certain transfer functions caused by said transmission of instruct-to-record information are described more fully below in "Operating Signal 35 Processing Systems ... 'Signal Record Transfer.'")

180

Then said process-monitor-info instructions cause onboard controller, 14A, to initiate a new monitor record that reflects the new "Wall Street Week" programming. Automatically, said instructions cause onboard controller, 5 14A, in a predetermined fashion, to delete all information at the monitor record location of said monitor record of prior programming except the source mark information associated with said record; to record information of said first named instance of "program unit identification code" information 10 (which is the "program unit identification code" of said "Wall Street Week" program to a particular "program unit identification code" location at said record location; to select particular information located at said SPAM-input-signal-@14A register memory and record information at said 15 record location; to select particular preprogrammed record format information that identifies the format of the information at said record location and place information of said information at a particular location at said record location and, separately, at a particular format comparison 20 location; and finally, to discard all unrecorded information of said 1st monitor information (#3) and commence waiting for the next inputted instance of monitor information.

The content of the 1st monitor information (#3) [more particularly, the information of the command execution 25 segment and of the meter-monitor format field] causes onboard controller, 14A, to organize the information of said new monitor record in a particular fashion. The command execution segment of the 1st monitor information (#3) causes signal processor, 200, to assemble the this new monitor 30 record in a particular format of a combined video/computer medium display and to include a particular record format field within said format identifying the format of said record. (Were the execution segment of said command of the aforementioned pseudo command, signal processor, 200, would 35 initiate a record for a 'conventional television program.)

181

From the command meter-monitor segment of the 1st monitor information (#3), onboard controller, 14A, selects and records at particular signal record field locations at said record location the information that identifies the program 5 unit of the particular "Wall Street Week" program, the origin of the "Wall Street Week" transmission, and the day of the particular transmission within a one hundred year period. In a predetermined fashion, onboard controller, 14A, also records in a particular monitor record field location at said 10 record location a particular display unit identification code that identifies monitor, 202M, as the display apparatus of said new monitor record. In a predetermined fashion, signal processor, 200, records date and time information received from clock, 18, in first and last particular time field 15 locations at said record location that document the date and time respectively of the first and of the last received instances of monitor information of the particular program unit and source mark.

20 OPERATING S. P. SYSTEMS ... EXAMPLE #3 (SECOND MESSAGE)

Subsequently, the embedded information of the second message of the "Wall Street Week" program is inputted to decoder, 203. Receiving said embedded information at decoder, 203, causes the SPAM information of said second 25 message to be detected at detector 34; inputted to controller, 39, at buffer, 39A; checked and corrected, as necessary, at processor, 39B; converted into locally usable binary information at processor, 39D; and processed by EOFs valve, 39F, in the end of file signal detecting fashion of 30 said valve, 39F, with all these functions occurring in the same fashions that applied to the SPAM information of the first message.

When EOFs valve, 39F, commences transferring the SPAM information of the second message, receiving the information 35 of the header of said message causes control processor, 39J,

182

to commence processing the information of said message under control of the preprogrammed instructions at the RAM and ROM associated with said processor, 39J, and to process, in particular, the information of said header. Automatically, 5 control processor, 39J, accepts the smallest number of signal words that can contain one instance of header information, records the information of said words in sequence at SPAM-input-signal register memory, then ceases accepting SPAM signal information transferred from EOFs valve, 39F.

10 Automatically, control processor, 39J, selects information of the first H bits at said SPAM-input-signal memory and records said information of H bits at SPAM-header memory then compares the information at said SPAM-header memory to the aforementioned 11-header-invoking information that is "11".

15 No match results.

Not resulting in a match causes control processor, 39J, first, to execute the aforementioned evaluate-message-content instructions then to receive and process the execution segment information in said second message.

20 Automatically, control processor, 39J, compares the information at said SPAM-header memory with preprogrammed invoke-monitor-processing information. A match results with particular "00" information. Said match signifies the presence of meter-monitor information in said second message and causes control processor, 39J, to enter "0" at SPAM-Flag-monitor-info register memory that is normally "1". Then, 25 automatically, control processor, 39J, commences accepting additional SPAM signal words from EOFs valve, 39F; receives and records additional words at said SPAM-input-signal

30 memory, in sequence after the information already there, until the total quantity of SPAM signal words recorded at said memory equals the smallest number of signal words that can contain one instance of header and execution segment information; then ceases accepting SPAM signal information

35 from EOFs valve, 39F. Automatically, control processor, 39J,

183

selects information of the first X bits of information at said SPAM-input-signal memory immediately after the first H bits, records said information of X bits at said SPAM-exec memory, and compares the information at said SPAM-exec memory with controlled-function-invoking information that is preprogrammed at the RAM and/or ROM associated with said processor, 39J. A match results with the aforementioned execute-conditional-overlay-at-205 information that is identical to the execute-conditional-overlay-at-205 information preprogrammed at SPAM-controller, 205C, of example #1. Said match causes control processor, 39J, to execute the aforementioned conditional-overlay-at-205 instructions. Said instructions cause SPAM-controller, 205C, to execute "GRAPHICS ON" at the PC-MicroKey System of microcomputer, 205, if the information of the program unit field in the meter-monitor information of said second message matches the information at said SPAM-first-precondition register memory and the information of the overlay number field in said meter-monitor information matches the information at said SPAM-second-precondition register memory.

Automatically, said conditional-overlay-at-205 instructions cause control processor, 39J, to receive and process the length token information in said second message. Automatically, control processor, 39J, recommences accepting additional SPAM signal words from EOFs valve, 39F; receives and records additional words at said SPAM-input-signal memory, in sequence after the information already there, until the total quantity of SPAM signal words recorded at said memory equals the smallest number of signal words that can contain one instance of header, execution segment, and length token information; then ceases accepting SPAM signal information from EOFs valve, 39F. Under control of the same preprogrammed instructions that controlled the processing of the length token of the first message, control processor, 39J, processes the length token of the second message in the

184

same fashion that applied to the first message but with one exception. Control processor, 39J, determines that the length token of said second message matches X-token information, when compared with token-comparison information, rather than Y-token information (which was the information matched by the length token information of the second message of example #2). Said match causes control processor, 39J, to select x-bits information, place said information at SPAM-length-info memory, and process said x-bits information as the numeric value of MMS-L. Then, in precisely the same fashion that applied in the case of the first message, control processor, 39J, determines a particular number of signal words to transfer and places information of said number at particular working register memory.

Next said conditional-overlay-at-205 instructions cause control processor, 39J, to receive all remaining command information and padding bits of said second message and to load said information and bits at said SPAM-input-signal memory in precisely the same fashion that applied in the case of the first message. Automatically, control processor, 39J, recommences accepting additional SPAM signal words from EOFs valve, 39F, and receives and records additional words at said SPAM-input-signal memory, in sequence after the information already there, until the total quantity of SPAM signal words recorded at said memory equals the number at said working register memory. Then, if the command information in said second message does not fill a whole number of signal words exactly, control processor, 39J, automatically ceases accepting SPAM signal information from EOFs valve, 39F. But if, instead, said command information does fill a whole number of signal words exactly, automatically control processor, 39J, receives one additional signal word from EOFs valve, 39F; compares said word to information of one EOFs WORD; records said word at said SPAM-input-signal memory immediately following the information

185

already recorded at said memory; receives one more signal word from EOFs valve, 39F, and records said word at said SPAM-input-signal memory immediately following the information of said one additional signal word if said  
5 additional word matched said information of one EOFs WORD at the aforementioned comparing; and ceases accepting SPAM signal information from EOFs valve, 39F.

By receiving all command information and padding bits in said second message, control processor, 39J, causes EOFs  
10 valve, 39F, to transfer every signal word in said message. Accordingly, the next signal word to be transferred by said valve, 39F, is the first word of the next message embedded in the "Wall Street Week" programming transmission after said second message.

15 Then, in order to locate the information of the program unit and overlay number fields in the meter-monitor information of said second message, said conditional-overlay-at-205 instructions cause control processor, 39J, to execute said evaluate-meter-monitor-format instructions and said  
20 instructions cause control processor, 39J, to place a selected offset-address number at SPAM-mm-format memory in the same fashion that applied in the case of the first message. Automatically, control processor, 39J, selects information of the bits of the meter-monitor format field in  
25 said first message, records said information at SPAM-mm-format register memory, compares the information at said memory with format-specification information, determines a match with B-format information that invokes process-B-format instructions that cause control processor, 39J, to place at  
30 said SPAM-mm-format memory a particular B-offset-address number that is different from the aforementioned A-offset-address number and that specifies the RAM address/location of the first bit of information that identifies the specific format of the meter-monitor segment in said second message.

35 Then said conditional-overlay-at-205 instructions

cause control processor, 39J, to execute the aforementioned locate-program-unit instructions and locate the program unit field in the meter-monitor information of said second message in the same fashion that applied in the case of the first message. Automatically, controller, 39J, adds the  
5 aforementioned program-unit-field-start-datum-location number to information of said B-offset-address number and records the resulting first sum then adds the aforementioned program-unit-field-length-datum-location number to information of  
10 said B-offset-address number and records the resulting second sum. Next said instructions cause control processor, 39J, to select information of the starting bit location of said program unit field which information is the number of bit locations from the first bit location at said SPAM-input-  
15 signal memory to the first bit location of said field. Automatically, control processor, 39J, places said information at first-working register memory then selects second information of the length of said program unit field in contiguous bit locations and places said second  
20 information at second-working register memory. Automatically, control processor, 39J, selects binary information of the second-working memory information number of contiguous bit locations at said SPAM-input-signal memory that begin at the first-working memory information number of  
25 bit locations after the first bit location at said memory. Automatically, control processor, 39J, places said binary information at said first-working memory. In so doing, control processor, 39J, places at said memory information of the the unique "program unit identification code" that  
30 identifies the program unit of said "Wall Street Week" program.

Then said conditional-overlay-at-205 instructions cause control processor, 39J, to compare the information at said first-working memory to the information at the  
35 aforementioned SPAM-first-precondition register memory (which

187

is the same unique code). A match results (which indicates that control processor, 39J, executed the aforementioned load-run-and-code instructions under control of the first message.) Said match causes control processor, 39J, to  
5 continue executing said conditional-overlay-at-205 instructions.

(As described in the case of the second message of example #1, at any subscriber station where information at first-working register memory fails to match information at  
10 SPAM-first-precondition register memory, said failing to match causes the control processor, 39J, of said station to clear all SPAM information from main and video RAMs of the microcomputers, 205, of said stations and, themselves, to discard all information of said second message and commence  
15 waiting for the binary information of a subsequent SPAM header.)

Next said conditional-overlay-at-205 instructions cause control processor, 39J, to execute the aforementioned locate-overlay-number instructions and locate the overlay  
20 number field in said meter-monitor information in the same fashion that the information of the program unit field is located. Said locate-overlay-number instructions cause controller, 39J, to add a particular preprogrammed overlay-number-field-start-datum-location number (that is different  
25 from the aforementioned program-unit-field-start-datum-location number) to information of said B-offset-address number and record the resulting first sum then add a particular preprogrammed overlay-number-field-length-datum-location number to information of said B-offset-address  
30 number and record the resulting second sum. Next said instructions cause control processor, 39J, to select preprogrammed binary information of the aforementioned datum-cell-length number of contiguous bit locations that begin at said first sum number of bit locations after the  
35 aforementioned first-bit location at said RAM and place said

188

binary information at first-working register memory and to select preprogrammed binary information of said datum-cell-length number of contiguous bit locations that begin at said second sum number of locations after said first-bit location  
5 and place said binary information at second-working register memory. In so doing, control processor, 39J, places at said first-working memory information of the bit distance from the first bit location of said SPAM-input-signal memory to the first bit location of said overlay number field and places at  
10 said second-working memory information of the number of contiguous bit locations in said overlay number field. Automatically, control processor, 39J, selects binary information of the second-working memory information number of contiguous bit locations at said SPAM-input-signal memory  
15 that begin at the first-working memory information number of bit locations after the first bit location at said memory. Automatically, control processor, 39J, places said binary information at said first-working memory (thereby overwriting and obliterating the information previously there). In so  
20 doing, control processor, 39J, selects from the information at said SPAM-input-signal memory and records at said first-working memory the information of said overlay number field. (After the information of said overlay field is placed at said memory, the information at said memory is "00000001".)

25 Then said conditional-overlay-at-205 instructions cause control processor, 39J, to compare the information at said first-working memory to the "00000001" information at the aforementioned SPAM-second-precondition register memory. A match results (indicating that microcomputer, 205, has  
30 completed placing appropriate Fig. 1A image information at video RAM).

(As described in the case of the second message of example #1, at any subscriber station where information at first-working register memory fails to match information at  
35 SPAM-second-precondition memory, the control processor, 39J,

189

of said station interrupts the operation of the CPU of said microcomputer, 205, in an interrupt fashion well known in the art, and causes said microcomputer, 205, to restore efficient operation in a fashion described more fully below.)

5       At the subscriber station of Fig. 3 (and at URS microcomputers, 205, at other subscriber stations where information at first-working memory matches information at SPAM-second-precondition memory), said match causes control processor, 39J, to cause matrix switch, 39I, to cease  
10 transferring information from EOFS valve, 39F, to control processor, 39J, and commence transferring information from control processor, 39J, to the PC-MicroKey System of microcomputer, 205; to transmit the instruction, "GRAPHICS ON", to said PC-MicroKey System; and to complete said  
15 conditional-overlay-at-205 instructions, the controlled functions of the second combining synch command, and the controlled functions of said second message.

At the subscriber station of Fig. 3 (and at URS microcomputers, 205, at other subscriber stations), said  
20 instruction, "GRAPHICS ON", causes said PC-MicroKey System to combine the programming of Fig. 1A and of Fig. 1B and transmit the combined programming to monitor, 202M, where Fig. 1C is displayed.

Automatically, the preprogrammed instructions that  
25 control control processor, 39J, cause said processor, 39J, to prepare to receive the next SPAM message. Automatically, control processor, 39J, determines, in a predetermined fashion, that EOFS valve, 39F, is the primary input to control processor, 39J, of SPAM message information; causes  
30 matrix switch, 39I, to commence transferring information from EOFS valve, 39F, to control processor, 39J; determines that the information at said SPAM-header memory does not match the aforementioned cause-retention-of-exec information that is "01".

35       Then, being preprogrammed to collect monitor

190

information, control processor, 39J, automatically compares the information at said SPAM-Flag-monitor-info memory with particular preprogrammed "0" information. A match results. Said match causes control processor, 39J, to execute 5 particular ones of its preprogrammed collect-monitor-information instructions. Under control of said ones, control processor, 39J, transfers to the buffer/comparator, 14, of signal processor, 200, header information that identifies a transmission of monitor information then the 10 aforementioned decoder-203 source mark information then all of the received binary information of said second message that is recorded at said SPAM-input-signal memory. (Said information is complete information of the second combining synch command, and said information transmitted to 15 buffer/comparator, 14, is called, hereinafter, the "2nd monitor information (#3).") Then control processor, 39J, enters "1" at said SPAM-Flag-monitor-info memory, completes said collect-monitor-info instructions, and continues the conventional preprogrammed instructions of said control 20 processor, 39J.

Automatically control processor, 39J, deletes from memory all information of said second message and commences waiting to receive the binary information of a subsequent SPAM header from matrix switch, 39I.

25 At signal processor, 200, receiving said 2nd monitor information (#3) causes buffer/comparator, 14, to determine that the header information, in said 2nd monitor information (#3), that identifies a transmission of monitor information matches the aforementioned monitored-instruction-fulfilled- 30 identification information which causes buffer/comparator, 14, to input said 2nd monitor information (#3) to onboard controller, 14A.

Receiving said 2nd monitor information (#3) causes onboard controller, 14A, to record the source mark 35 information in said 2nd monitor information (#3) at source-

191

mark-@14A register memory; to record, at particular SPAM-  
input-signal-@14A register memory, all of the received binary  
information of said first message that was recorded at the  
aforementioned SPAM-input-signal memory of controller, 39J;  
5 and to execute the aforementioned process-monitor-info  
instructions. Said instructions cause onboard controller,  
14A, to compare the information at said source-mark-@14A  
memory with the aforementioned source-identification  
information. A match results with the aforementioned  
10 decoder-203 source mark information. Said match causes  
onboard controller, 14A, to locate the instance of "program  
unit identification code" information at said SPAM-input-  
signal-@14A register memory, in the fashion described above;  
to locate the instance of "program unit identification code"  
15 information in the aforementioned new monitor record; and to  
compare said first named instance to said second named  
instance. A match results. Under control of said process-  
monitor-info instructions, said match causes onboard  
controller, 14A, to record date and time information,  
20 received from clock, 18, at the aforementioned last  
particular time field of said new monitor record and, in a  
predetermined fashion, to compare the meter-monitor format  
field at said SPAM-input-signal-@14A register memory to the  
aforementioned record format field associated with said  
25 monitor record. No match results which indicates that said  
2nd monitor information (#3) contains new information. Not  
resulting in a match causes onboard controller, 14A, in a  
predetermined fashion, to evaluate said new information and  
modify the information content of said new monitor record by  
30 adding and/or deleting and/or replacing information. One  
element of information modified at said new monitor record is  
said record format information which is replaced with new  
record format information that specifies the format in which  
the information of said new record is organized. Finally,  
35 said process-monitor-info instructions cause onboard

192

controller, 14A, to discard all unrecorded information of said 2nd monitor information (#3) and commence waiting for the next inputted instance of monitor information.

The new information content of the 2nd monitor  
5 information (#3) causes controller, 20, to modify the information of said new monitor record in a particular fashion. The command meter-monitor segment information of the minute of the particular transmission within a particular one month period provides new information. By comparing said  
10 information with date and time information from clock, 18, in a predetermined fashion, controller, 20, determines whether said "Wall Street Week" programming is being displayed at the time of its original transmission or whether it has been so-called "time shifted"; that is, recorded at one time and a  
15 receiver station video tape recorder and played back at a subsequent time. If controller, 20, determines that the time of clock, 18, is the time of original transmission (plus or minus particular error parameter information), controller, 20, deletes the information of the day of the particular  
20 transmission within a one hundred year period from said monitor record, modifies the record format field with information that distinguishes said new record as a record of a display of an original transmission, and enters all other recorded information of said new monitor record into the  
25 particular fields of said format. If controller, 20, determines that the original transmission has been time shifted, controller, 20, modifies the record format field with information that distinguishes said new record as a record of a time shifted display, enters all previously  
30 recorded information within the proper fields of said format, and records the new information of the minute of the particular transmission within a particular one month period.

The particular overlay information of the command meter-monitor segment of the 2nd monitor information (#3)  
35 also provides new information. Controller, 20, uses said

193

particular overlay information in several fashions. It records in a particular field of said new monitor record a count, starting with "1" for said first overlay, of the number of overlays processed in the course of said program unit. It increments by one a separate monitor record count of the aggregate number of overlays displayed at monitor, 202M, over a particular calendar month period. And it increments by one a separate monitor record count of the aggregate number of combinings processed by all receiver station apparatus over a particular time period.

## OPERATING S. P. SYSTEMS ... EXAMPLE #3 (THIRD MESSAGE)

Subsequently, the embedded information of the third message of the "Wall Street Week" program is inputted to decoder, 203. Just as with the information of the first and second messages, receiving the embedded information of said third message causes the SPAM information of said message to be detected at detector, 34, and inputted to controller, 39, at buffer, 39A; checked and corrected, as necessary, at processor, 39B; converted into locally usable binary information at processor, 39D; and processed for end of file signal information at EOFS valve, 39F.

When EOFS valve, 39F, commences transferring the SPAM information of said third message, control processor, 39J, automatically accepts the smallest number of signal words that can contain one instance of header information, records the information of said words in sequence at SPAM-input-signal register memory, then ceases accepting SPAM signal information transferred from EOFS valve, 39F. Automatically, control processor, 39J, selects information of the first H bits at said SPAM-input-signal memory, records said information of H bits at SPAM-header memory, and compares the information at said SPAM-header memory to the aforementioned 11-header-invoking information that is "11". No match results.

194

Not resulting in a match causes control processor, 39J, first, to execute evaluate-message-content instructions then to receive and process the execution segment information in said third message. Automatically, control processor, 5 39J, compares the information at said SPAM-header memory with preprogrammed invoke-monitor-processing information. No match results which signifies the absence of meter-monitor information in said third message. Accordingly, the information at said SPAM-Flag-monitor-info register memory 10 remains "1". Then control processor, 39J, recommences accepting additional SPAM signal words from EOFs valve, 39F; receives and records additional words at said SPAM-input-signal memory, in sequence after the information already there, until the total quantity of SPAM signal words recorded 15 at said memory equals the smallest number of signal words that can contain one instance of header and execution segment information; then ceases accepting SPAM signal information from EOFs valve, 39F. Automatically, control processor, 39J, selects information of the first X bits of information at 20 said SPAM-input-signal memory immediately after the first H bits, records said information of X bits at said SPAM-exec memory, and compares the information at said SPAM-exec memory with controlled-function-invoking information that is preprogrammed at the RAM and/or ROM associated with said 25 processor, 39J. A match results with the aforementioned cease-overlay information causing control processor, 39J, to execute the aforementioned cease-overlaying-at-205 instructions.

Automatically, said instructions cause control 30 processor, 39J, to cause matrix switch, 39I, to cease transferring information from EOFs valve, 39F, to control processor, 39J, and commence transferring information from control processor, 39J, to the PC-MicroKey System of microcomputer, 205; to transmit the instruction, "GRAPHICS 35 OFF", to said PC-MicroKey System; to cause matrix switch,

195

39I, to cease transferring information from control processor, 39J, to said PC-MicroKey System and commence transferring information from control processor, 39J, to the CPU of microcomputer, 205; then to transmit the  
5 aforementioned clear-and-continue instruction (the function of which is described more fully below) to said CPU; and finally, to cause matrix switch, 39I, to cease transferring information from control processor, 39J, to said CPU. In so doing, control processor, 39J, completes said cease-  
10 overlaying-at-205 instructions.

At the subscriber station of Fig. 3 (and at URS microcomputers, 205, at other subscriber stations), said instruction, "GRAPHICS OFF", causes said PC-MicroKey System to cease combining the programming of Fig. 1A and of Fig. 1B  
15 and commence transmitting to monitor, 202M, only the composite video programming received from divider, 4, (which causes monitor, 202M, to commence displaying only said video programming). And said clear-and-continue instruction causes microcomputer, 205, to commence processing in a predetermined  
20 fashion (which fashion may be determined by the aforementioned program instruction set).

Having completed the controlled functions of said third message, the conventional control instructions that control control processor, 39J, cause said processor, 39J to  
25 prepare to receive the next instance of SPAM message information in the following fashion.

Automatically, control processor, 39J, determines, in a predetermined fashion, that EOFs valve, 39F, is the primary input to control processor, 39J, of SPAM message information;  
30 causes matrix switch, 39I, to commence transferring information from EOFs valve, 39F, to control processor, 39J; determines that the information at said SPAM-header memory does not match said cause-retention-of-exec information that is "01"; then, being preprogrammed to collect monitor  
35 information, compares the information at said SPAM-Flag-

196

monitor-info memory with particular preprogrammed "0" information. No match results, and receiving said third message does not cause control processor, 39J, to transmit monitor information to buffer/comparator, 14, of signal processor, 200. Automatically, control processor, 39J, completes said collect-monitor-info instructions and continues the conventional preprogrammed instructions of said control processor, 39J.

Automatically control processor, 39J, deletes from memory all information of said third message, but in so doing, control processor, 39J, may perform particular functions that are not performed in deleting from memory information of the first and second messages. Control processor, 39J, has received all command information in said third message but may not have received all padding bits. If the command information in the smallest number of signal words that can contain one instance of header and execution segment information fills a whole number of signal words exactly, the last signal word of said command information may contain no MOVE bits and be followed by one full signal word of padding bits. To ensure that all padding bits of said third message are transferred from EOFs valve, 39F, control processor, 39J, is preprogrammed with particular additional conventional instructions if H+X fills a whole number of signal words exactly. Before information of said third message at said SPAM-header memory is deleted, said particular instructions cause control processor, 39J, to compare said information to particular preprogrammed "10" information. A match results which causes control processor, 39J, under control of said particular instructions, to compare the last signal word of information at said SPAM-input-signal memory to information of one EOFs WORD; to receive one additional signal word from EOFs valve, 39F, if said last word matches said information of one EOFs WORD; then to cease accepting SPAM signal information from EOFs

197

valve, 39F. In this fashion, control processor, 39J, ensures automatically that the next signal word to be transferred by said valve, 39F, will be the first word of the next message embedded in the "Wall Street Week" programming transmission 5 after said third message.

Then, having deleted from memory all information of said third message, automatically control processor, 39J, commences waiting to receive the binary information of a subsequent SPAM header from matrix switch, 39I.

10

#### OPERATING SIGNAL PROCESSOR SYSTEMS ... EXAMPLE #4

In example #4, the first and second messages are both partially encrypted, and the combining of Fig. 1A and Fig. 1B information occurs only at selected subscriber stations where 15 the information of said messages causes decrypting and collecting of meter information as well as combining. In addition, the information of said messages also causes the collecting of monitor information at selected ones of said selected stations which selected ones are preprogrammed to 20 collect monitor information in the fashion of example #3. In example #4, all appropriate apparatus of the subscriber station of Fig. 3 are preprogrammed to collect monitor information, and buffer/comparator, 14, operates under control of the aforementioned on-board controller, 14A, in 25 fashions elaborated on below.

Example #4 elaborates on the process of monitor information collection in one particular respect. The second message of example #2 causes particular monitor information to be recorded at those particular stations, preprogrammed to 30 collect monitor information, where microcomputers, 205, fail to satisfy either condition of the invoked conditional-overlay-at-205 instructions. Thus the monitor information collected in example #4 documents not only what programming is displayed at the subscriber station monitors, 202M, of the 35 present invention but also the efficiency of the operation of

198

the system of subscriber station microcomputers, 205. Said monitor information also provides statistics on those particular subscriber stations that tune to and process the programming of said "Wall Street Week" program but cannot display Fig. 1C combined medium image information because said particular stations are preprogrammed with decryption key information of J but not of Z. Such statistics enable programming suppliers to evaluate their strategies for marketing and pricing programming.

10 In example #4, before the first message is embedded at the "Wall Street Week" program originating studio and transmitted, all information of the execution segment, the meter-monitor segment, and the program instruction set in the information segment are encrypted, using standard encryption techniques that encrypt binary information without altering the number of bits in said information. However, the cadence information of said message remains unencrypted. More precisely, the "01" header, any padding bits added at the end of the information segment, and the end of file signal that ends said message remain unencrypted. (The length token and any padding bits at the end of the command information in a message that ends with an end of file signal are not, strictly speaking, cadence information because they provide no information as to the location of the header that follows such a message.) Like the second message of example #2, the first message of example #4 is only partially encrypted in order to enable subscriber stations that lack capacity to decrypt said message to process accurately the cadence information of said message.

30 In example #4, the encryption of the execution segment of said first message is done in such a fashion that, after encryption, said segment is identical to a particular execution segment that addresses URS signal processors, 200, and instructs said processors, 200, to use a particular decryption key Z (different from the decryption key J that

199

decrypted the second message of example #2) and decrypt the message in which said segment occurs.

Because said first message is encrypted, its meter-monitor segment contains a seventh field: a meter instruction field. Accordingly, the length of said first message, the number of bits in its meter-monitor segment, the information of the meter-monitor format field, and the numeric value of MMS-L is greater in example #4 than in example #1 and example #3.

10 As described above in "One Combined Medium," before any messages of the "Wall Street Week" programming are transmitted, control invoking instructions are embedded at said program originating studio and transmitted to all subscriber stations. Among said instructions are particular  
15 instructions, cited in example #2, that set PC-MicroKey Model 1300 Systems to the "Graphics Off" mode, and also instructions that command URS microcomputers, 205, to clear all RAM (except RAM containing operating system information). In addition (and not described in "One Combined Medium"),  
20 said instructions also include particular instructions that cause information of zero to be placed at the aforementioned SPAM-first-precondition and SPAM-second-precondition register memories. Accordingly, at the outset of example #4, no PC-MicroKey 1300 is in "Graphics On" mode; no microcomputer,  
25 205, contains any image information at video RAM; and no "program unit identification code" information exists at the SPAM-first-precondition register memory of any control processor, 39J.

At the outset of example #4, information of "1" is at  
30 each of the aforementioned SPAM-Flag-monitor-info, SPAM-Flag-at-secondary-control-level, SPAM-Flag-executing-secondary-command, SPAM-Flag-secondary-level-incomplete, SPAM-Flag-primary-level-2nd-step-incomplete, SPAM-Flag-primary-level-3rd-step-incomplete, SPAM-Flag-secondary-level-2nd-step-  
35 incomplete, SPAM-Flag-secondary-level-3rd-step-incomplete,

200

SPAM-Flag-first-condition-failed, SPAM-Flag-second-condition-failed, and SPAM-Flag-do-not-meter register memories, and matrix switch, 39I is configured to transfer SPAM message information from EOFs valve, 39F, to control processor, 39J.

5        Example #4 begins, like example #3, with divider, 4, transferring the embedded information of said first message to decoder, 203. In the same fashion that applied in example #3, receiving said embedded information at decoder, 203, causes the binary SPAM information of said first message to  
10 be received, with error correcting information, at decoder, 203; detected at detector, 34; inputted to controller, 39, at buffer, 39A; checked and corrected, as necessary, at processor, 39B; converted into locally usable binary information at processor, 39D; and processed for end of file  
15 signal information at EOFs valve, 39F.

Receiving said first message causes the apparatus of the station of Fig. 3, in the following fashion, to decrypt the encrypted portions of said message; to execute the controlled functions of the decrypted information of said  
20 message; to collect meter information and monitor information relating to said message; and in the fashion described more fully below in "Operating Signal Processing Systems ... Signal Record Transfer," to transfer meter information and monitor information to one or more remote processing  
25 stations, causing said stations to process said information.

When EOFs valve, 39F, commences transferring the SPAM message information of said first message, control processor, 39J, automatically accepts the smallest number of signal words that can contain H bits; records the information of  
30 said words at SPAM-input-signal register memory; ceases accepting SPAM message information from EOFs valve, 39F; selects information of the first H bits at said SPAM-input-signal memory; records said information at SPAM-header memory; and compares the information recorded at said memory  
35 to the aforementioned 11-header-invoking information that is

201

"11". No match results.

Not resulting in a match causes control processor, 39J, first, to execute the aforementioned evaluate-message-content instructions (because the stations of Fig. 3 is  
5 preprogrammed to collect monitor information) then to receive and process the execution segment information in said first message. Automatically, control processor, 39J, compares the information at said SPAM-header memory with preprogrammed invoke-monitor-processing information. A match results with  
10 particular "01" information. Said match signifies the presence of meter-monitor information (albeit encrypted) in said first message and causes control processor, 39J, to enter "0" at the aforementioned SPAM-Flag-monitor-info register memory. Then control processor, 39J, recommences  
15 accepting additional SPAM signal words from EOFS valve, 39F; receives and records said words at said SPAM-input-signal memory, in sequence after the information already there, until the total quantity of SPAM signal words recorded at said memory equals the smallest number of signal words that  
20 can contain H+X bits; ceases accepting SPAM signal information from EOFS valve, 39F; selects information of the first X bits of information at said SPAM-input-signal memory immediately after the first H bits; records said information at said SPAM-exec memory, and compares the information at  
25 said memory with the aforementioned controlled-function-invoking information. A match results with particular preprogrammed this-message-addressed-to-200 information.

In examples #1 and #2, whenever controller, 39, determined matches with either this-message-addressed-to-205  
30 information or this-message-addressed-to-200 information, controller, 39, transferred the entire message containing the identified information to the addressed apparatus. But in the preferred embodiment, controller, 39, may be preprogrammed to transfer, by control information  
35 transmission means, only particular information of any given

202

message that contains this-message-addressed-to-200 information. The first and second messages of example #4 illustrate instances of such transferring.

Said match with this-message-addressed-to-200  
5 information causes control processor, 39J, automatically to execute particular preprogrammed transfer-header-and-exec-seg-info-to-200 instructions. Automatically, said instructions cause control processor, 39J, to transfer to controller, 20, of signal processor, 200, via control  
10 information transmission means, an interrupt signal that interrupts the operation of said controller, 20, in a fashion well known in the art, then particular process-this-message information then particular at-39J information that identifies control processor, 39J, as the source of the  
15 transmission of said process-this-message information then information of the header and execution segment of said first message (that is, information of the information recorded at said SPAM-header and SPAM-exec memories).

Receiving said interrupt signal and information causes  
20 controller, 20, to compare the information of said execution segment to the aforementioned controlled-function-invoking-@200 information and determine a match with particular decrypt-with-key-Z information that instructs controller, 20, to cause the decryption of the received binary signal  
25 information of said first message with decryption key Z.

(At subscriber stations whose URS signal processors, 200, are not preprogrammed with information of said key Z, the information of said execution segment fails to match any controlled-function-invoking-@200 information.  
30 Automatically, failing to match causes the controllers, 20, of said stations to cause the control processors, 39J, of said stations to discard all information of said first message by causing matrix switch, 39I, to transfer all information inputted from EOFS valve, 39F, to its null  
35 output; then causing EOFS valve, 39F, to transfer all

203

received SPAM information until an end of file signal is detected; then, after said signal is detected, causing said valve, 39F, to discard its recorded information of said end of file signal; causing matrix switch, 39I, to commence  
5 transferring all information inputted from EOFs valve, 39F, to control processor, 39J; and, itself, deleting all recorded information of said message and commencing to wait for inputted information of a SPAM header.)

However, the subscriber station of Fig. 3 is  
10 preprogrammed with all information needed to decrypt said first message. The aforementioned at-39J information and match with decrypt-with-key-Z information cause controller, 20, to execute particular preprogrammed decrypt-with-Z-at-39K instructions. Said instructions cause controller, 20, to  
15 select particular preprogrammed key information of Z and transfer said key information to decryptor, 39K, of controller, 39. Then said decrypt-with-Z-at-39K instructions cause controller, 20, to compare said information of the header transferred from control processor, 39J, to particular  
20 preprogrammed header-identification-@200 information and to determine that said information of the header matches particular "01" header information. Said match causes controller, 20, automatically to transmit a particular decrypt-in-a-01-or-11-header-message-fashion instruction to  
25 decryptor, 39K.

Receiving said key information and said last named instruction causes decryptor, 39K, to commence using said key information as its key for decryption and decrypting inputted information in a predetermined 01-or-11-header-message  
30 fashion that is described more fully below.

Then said decrypt-with-Z-at-39K instructions cause controller, 20, to transmit to control processor, 39J, a particular decrypt-process-and-meter-a-01-or-11-header-message instruction and particular decryption mark  
35 information of key Z that identifies Z as the decryption key.

204

Receiving said instruction and mark information causes control processor, 39J, to record said mark information at the aforementioned SPAM-decryption-mark register memory, to enter "1" at the aforementioned SPAM-Flag-monitor-info  
5 register memory because any meter-monitor information in the SPAM message being processed is encrypted, then to execute particular preprogrammed decrypt-process-and-meter-current-01-or-11-header-message instructions.

Said instructions cause control processor, 39J, first,  
10 to identify EOFs valve, 39F, in a predetermined fashion, as the primary source of input SPAM message information; to place particular from-39F information at the aforementioned SPAM-primary-input-source register memory; and to place information of a particular reentry-address at the  
15 aforementioned SPAM-address-of-next-instruction-upon-primary-interrupt register memory which reentry-address specifies the location of the next decrypt-process-and-meter-current-01-or-11-header-message instruction to be executed when interrupt information of end of file signal detected information is  
20 next received by control processor, 39J, from said primary source of input SPAM message information, EOFs valve, 39F.

Then said instructions cause control processor, 39J, to transfer to decryptor, 39K, the SPAM message associated with the particular information at the SPAM-header memory of control processor, 39J. Automatically, said instructions  
25 cause control processor, 39J, to cause matrix switch, 39I, to cease transferring information from EOFs valve, 39F, to control processor, 39J, and commence transferring information from control processor, 39J, to decryptor, 39K. Then said  
30 instructions cause control processor, 39J, to transfer all SPAM message information recorded at said SPAM-input-signal memory of control processor, 39J. Said information is all the information of said first message that EOFs valve, 39F, has already transferred. Automatically, decryptor, 39K,  
35 commences receiving SPAM signal information. Then said

205

instructions cause control processor, 39J, to cause matrix switch, 39I, to cease transferring information from control processor, 39J, to decryptor, 39K, and to commence transferring SPAM message information from EOFs valve, 39F, to decryptor, 39K. As decryptor, 39K, then accepts transferred information from matrix switch, 39I, automatically EOFs valve, 39F, commences transferring SPAM signal information, beginning with the first signal word of said first message that is immediately after the information of said first message that EOFs valve, 39F, has already transferred. In this fashion, control processor, 39J, causes all information of said first message to be transferred to decryptor, 39K.

Then said decrypt-process-and-meter-current-01-or-11-header-message instructions cause control processor, 39J, to prepare to receive the decrypted information of said first message and to execute, at a secondary control level under primary control of said decrypt-process-and-meter-current-01-or-11-header-message instructions, the controlled functions invoked by said decrypted information. Under control of said decrypt-process-and-meter-current-01-or-11-header-message instructions, control processor, 39J, places information of a particular reentry-address at the aforementioned SPAM-next-primary-instruction-address register memory which reentry-address specifies the location of the next decrypt-process-and-meter-current-01-or-11-header-message instruction to be executed when control of control processor, 39J, reverts from the secondary control level to the primary control level; places information of "0" at the aforementioned SPAM-Flag-primary-level-2nd-step-incomplete register memory and, separately, at SPAM-Flag-primary-level-3rd-step-incomplete register memory which information signifies that specific primary level functions have not been completed; places information of "0" at the aforementioned SPAM-Flag-secondary-level-incomplete register memory that is normally "1" which

206

information signifies that secondary control level functions have not been completed; compares the information at said SPAM-header memory to cause-retention-of-exec information that is "01" and places information of said information at  
5 SPAM-exec register memory at said SPAM-last-01-header-exec register memory because a match results; compares the information at said SPAM-Flag-monitor-info memory with particular preprogrammed "0" information and skips all steps of collecting monitor information because no match results;  
10 causes all apparatus of control processor, 39J, to delete from memory all information of said first message except information at said SPAM-last-01-header-exec, SPAM-decryption-mark, SPAM-Flag-at-secondary-control-level, SPAM-Flag-primary-level-2nd-step-incomplete, SPAM-Flag-primary-  
15 level-3rd-step-incomplete, SPAM-primary-input-source, SPAM-next-primary-instruction-address register memories; places particular from-39H information at the aforementioned SPAM-secondary-input-source register memory that identifies EOFs valve, 39H, as the secondary level source of input SPAM  
20 message information; causes matrix switch, 39I, to commence transferring SPAM message information from EOFs valve, 39H to control processor, 39J; places information of "0" at the aforementioned SPAM-Flag-executing-secondary-command register memory which information signifies that information placed  
25 subsequently at SPAM-exec register memory is secondary command level information; places information of "0" at the aforementioned SPAM-Flag-at-secondary-level register memory that is normally "1" which information signifies that control functions are being executed at said secondary level; and  
30 commences waiting to receive information of a subsequent SPAM header from said switch, 39I.

As decryptor, 39K, receives SPAM message information from matrix switch, 39I, decryptor, 39K, decrypts said information, using decryption key Z, in the aforementioned  
35 01-or-11-header-message fashion and transfers the decrypted

207

information to buffer, 39G. The aforementioned decrypt-in-a-01-or-11-header-message-fashion instruction causes decryptor, 39K, to transfer the first H bits received from matrix switch, 39I, without decrypting or altering said bits in any  
5 fashion then to decrypt and transfer all information following said first H bits. In this fashion, the cadence information of the header in said first message, which is not encrypted, is transferred by decryptor, 39K, to buffer, 39G, without alteration.

10 As buffer, 39G, receives said decrypted information, buffer, 39G, buffers said information and transfers it to EOFs valve, 39H. EOFs valve, 39H, checks said information for end of file signal information, in its preprogrammed end of file signal detection fashion, and transfers information  
15 that is not end of file signal, via matrix switch, 39I, to control processor, 39J, as fast as control processor, 39J, is prepared to receive said information.

Having been decrypted, said information is identical to the binary information of the first message of example #3  
20 (except that the meter-monitor information contains the aforementioned meter instruction information that is not in example #3 and the information of the meter-monitor format field reflects the presence of said instruction information). Accordingly, receiving the decrypted information of the first  
25 message of example #4 from EOFs valve, 39H, causes control processor, 39J, to function, at the aforementioned secondary control level, in fashions that are identical (except as concerns the processing of the meter-monitor information) to the fashions invoked, at the primary control level, by  
30 receiving the information of the first message of example #3 from EOFs valve, 39F.

When EOFs valve, 39H, commences transferring the decrypted SPAM information of the first message of example #4, control processor, 39J, receives the smallest number of  
35 signal words that can contain H bits, records information

208

said words in sequence at SPAM-input-signal memory, selects information of the first H bits at said memory, records said information at SPAM-header memory, and determines that the information at said memory does not match the aforementioned  
5 ll-header-invoking information.

Not resulting in a match causes control processor, 39J, automatically to compare the information at said SPAM-header memory with the aforementioned invoke-monitor-processing information, determine a match, and enter "0" at  
10 SPAM-Flag-monitor-info register memory.

Automatically, control processor, 39J, then receives additional SPAM signal words; records information of said words at said SPAM-input-signal memory in sequence immediately following the signal word information already  
15 recorded at said memory until the total quantity of SPAM signal words recorded at said memory is the smallest number of signal words that can contain H+X bits; selects information of the first X bits of information at said memory immediately after the first H bits, records said selected  
20 information at SPAM-exec memory, compares the information at said last named memory with controlled-function-invoking information, and determines a match with the aforementioned execute-at-205 information.

Said match causes control processor, 39J, to execute  
25 the aforementioned load-run-and-code instructions. Said instructions cause control processor, 39J, to determine that the information at said SPAM-Flag-at-secondary-level register memory is "0" which causes said processor, 39J, to place "0" at the aforementioned SPAM-Flag-secondary-level-2nd-step-  
30 incomplete register memory and, separately, at SPAM-Flag-secondary-level-3rd-step-incomplete register memory (rather than SPAM-Flag-primary-level-2nd-step-incomplete and SPAM-Flag-primary-level-3rd-step-incomplete memories) and to place information of a particular reentry-address at the  
35 aforementioned SPAM-address-of-next-instruction-upon-

209

secondary-interrupt register memory (rather than SPAM-address-of-next-instruction-upon-primary-interrupt memory). Then said instructions cause control processor, 39J, to compare the information at said SPAM-header memory with  
5 header-identification information and determine a match with "01" information.

Said match causes control processor, 39J, to receive all remaining command information and padding bits in said first message in the fashion that applies to a SPAM message  
10 that contains meter-monitor information. Automatically, control processor, 39J, receives and processes decrypted length token information. Automatically, control processor, 39J, receives and records additional SPAM signal words at said SPAM-input-signal memory until the quantity of SPAM  
15 words recorded at said memory is the smallest number of words that can contain  $H+X+L$  bits, selects information of the first  $L$  bits of information at said memory immediately after the first  $H+X$  bits, records said information at SPAM-length-info memory, determines that the information at said last named  
20 memory matches  $Z$ -token information, selects  $z$ -bits information associated with said  $Z$ -token information, records said  $z$ -bits information at said SPAM-length-info memory (thereby overwriting and obliterating the information previously at said memory), and processes the information at  
25 said memory as the numeric value of  $MMS-L$ . Automatically, control processor, 39J, adds  $H+X+L$  to the information of  $z$ -bits at said memory, divides the information of the resulting sum by the number of bits in one signal word, places a "0" at particular SPAM-Flag-working register memory if the  
30 information of the resulting quotient is a whole number or "1" at said SPAM-Flag-working memory if it is not. Automatically, control processor, 39J, determines a particular number of signal words to receive, commences receiving additional SPAM signal words, and records said  
35 words in sequence at said SPAM-input-signal memory

2/0

immediately following the last SPAM signal word previously recorded at said memory until the total quantity of SPAM signal words recorded at said memory equals the number at said working register memory. Then, if the information at  
5 said SPAM-Flag-working register memory is "0", control processor, 39J, ceases accepting SPAM signal information. Or, if the information at said SPAM-Flag-working register memory is not "0", control processor, 39J, receives one additional signal word, compares the information of said word  
10 to information of one EOFS WORD, records said word at said SPAM-input-signal memory immediately following the last SPAM signal word recorded at said memory, receives one more SPAM signal word and records the information of said word at said SPAM-input-signal memory immediately following the last SPAM  
15 signal word recorded at said memory if said one additional signal word has matched said EOFS WORD information, and ceases accepting SPAM signal information.

When control processor, 39J, ceases accepting SPAM signal information, said load-run-and-code instructions cause  
20 control processor, 39J, to commence loading information at the main RAM of microcomputer, 205. Automatically, control processor, 39J, causes matrix switch, 39I, to cease transferring information from EOFS valve, 39H, to control processor, 39J, and commence transferring information from  
25 control processor, 39J, to the CPU of microcomputer, 205; instructs said CPU to commence receiving information from matrix switch, 39I, and loading said information at particular main RAM; and causes matrix switch, 39I, to cease  
30 transferring information from control processor, 39J, to said CPU and commence transferring information from EOFS valve, 39H, to said CPU. Automatically, microcomputer, 205, commences receiving the information, beginning with the first signal word at EOFS valve, 39H, which is the decrypted  
information of the first word of the program instruction set  
35 in said first message. Automatically, microcomputer, 205,

211

loads the received information at particular main RAM in a fashion well known in the art.

Then said load-run-and-code instructions cause control processor, 39J, to execute the code portion of said  
5 instructions. In the same fashion that that applied in example #3, the instructions of said portion cause control processor, 39J, to determine that said first message contains meter-monitor information, to locate the "program unit  
identification code" information in the information at said  
10 SPAM-input-signal memory, and to record information of said "code" information at SPAM-first-precondition register memory. Said instructions cause control processor, 39J, to select information of bits of the meter-monitor format field  
at at said SPAM-input-signal memory, to record said  
15 information at SPAM-mm-format memory, to compare the information at said memory with the aforementioned format-specification information, to determine a match with C-format information, and to execute particular preprogrammed process-  
C-format instructions. Automatically, said last named  
20 instructions cause control processor, 39J, to place a particular C-offset-address number at SPAM-mm-format memory that identifies the address/location of the first bit of C format information. Then said instructions of the code  
portion cause control processor, 39J, to execute the  
25 aforementioned said locate-program-unit instructions; to select binary information of particular bit locations at said SPAM-input-signal memory, using the information of said C-offset-address number; and to place said selected information  
at said SPAM-first-precondition memory. Finally, said  
30 instructions of the code portion cause control processor, 39J, to determine, in a predetermined fashion, that control processor, 39J, is operating at secondary control level and place "1" at SPAM-Flag-secondary-level-3rd-step-incomplete  
register memory (rather than SPAM-Flag-primary-level-3rd-  
35 step-incomplete memory) signifying the completion of the code

2/2

step executed by said load-run-and-code instructions.

Next said load-run-and-code instructions control processor, 39J, to determine that the information at said SPAM-Flag-at-secondary-level register memory is "0" which  
5 signifies that the run portion of said instructions remain uncompleted and which causes control processor, 39J, in a predetermined fashion, to commence waiting for interrupt information of the end of file signal from the EOFs valve that is inputting SPAM signal information to control  
10 processor, 39J, which is EOFs valve, 39H.

Whenever the control processor, 39J, of the station of Fig. 3 is instructed to commence waiting, the conventional instructions that control said processor, 39J, cause said processor, 39J, to execute particular steps before actually  
15 commencing to wait. Example #3 showed one such step: execution of particular collect-monitor-info instructions. In the preferred embodiment, said conventional instructions cause control processor, 39J, to execute particular primary-level-? instructions before executing said collect-monitor-  
20 info instructions. Said primary-level-? instructions cause control processor, 39J, to compare the information at the aforementioned SPAM-Flag-at-secondary-control-level memory with particular preprogrammed "0" information. A match results which means that control processor, 39J, has been  
25 instructed to wait at a secondary control level and instructions may exist at the primary control level that control processor, 39J, should execute before commencing to wait. Accordingly, said match causes control processor, 39J, to place information of a particular reentry-address at the  
30 aforementioned SPAM-next-secondary-instruction-address register memory which reentry-address is the location of the next instruction to be executed when the control of control processor, 39J, reverts from primary control level instructions to the secondary level instructions; to place  
35 "1" at the aforementioned SPAM-Flag-at-secondary-control-

2/3

level memory signifying that control processor, 39J, is not operating at the secondary control level; and to commence executing control instructions beginning with that instruction whose particular address/location is the address/location of the information at the aforementioned SPAM-next-primary-instruction-address memory.

Automatically, the particular ones of said decrypt-process-and-meter-current-01-or-11-header-message instructions that begin at said address/location cause control processor, 39J, to execute the meter portion of said instructions. Under control of the instructions of said portion, control processor, 39J, compares the information at the aforementioned SPAM-decryption-mark register memory to particular preprogrammed information of zero. No match results. Not resulting in a match signifies the presence of decryption mark information and causes control processor, 39J, under control said instructions, to cause matrix switch, 39I, to commence transferring information from control processor, 39J, to the buffer/comparator, 14, of signal processor, 200; then to transfer header information that identifies a transmission of meter information then the aforementioned decoder-203 source mark information then information of the decryption mark of key Z information recorded at SPAM-decryption-mark register memory then all of the received binary information of said first message that is recorded at said SPAM-input-signal memory; then to cause matrix switch, 39I, to cease transferring information from control processor, 39J, to said buffer/comparator, 14. (Said received information is complete information of the first combining synch command of example #4, and said information that is transmitted to buffer/comparator, 14, is called, hereinafter, the "1st meter-monitor information (#4).") Then the instructions of said portion cause control processor, 39J, to enter "1" at said SPAM-Flag-monitor-info memory because the information of said 1st meter-monitor information

214

(#4) is monitor information as well as meter information, to enter "1" at the aforementioned SPAM-Flag-primary-level-3rd-step-incomplete register memory signifying the completion of the meter step executed by said decrypt-process-and-meter-  
5 current-01-or-11-header-message instructions, and to commence waiting for interrupt information of an end of file signal.

In due course, EOFS valve, 39F, receives the last signal word of the information segment of said first message, which is the last signal word of said program instruction  
10 set. Receiving said word causes EOFS valve, 39F, to transfer said word, via matrix switch, 39I, to decryptor, 39K, which causes decryptor, 39K, to decrypt the information of said word and transfer the decrypted information of said word, via buffer, 39G, to EOFS valve, 39H. If the decrypted  
15 information of said word contains MOVE bit information, receiving said information causes EOFS valve, 39H, to transfer said information, via matrix switch, 39I, to the CPU of microcomputer, 205, which causes microcomputer, 205, to load said information at particular main RAM.

20 Then said valve, 39F, commences receiving information of the eleven EOFS WORDs that constitute the end of file signal at the end of said first message.

Receiving the first EOFS WORD of said eleven causes EOFS valve, 39F, to cease transferring SPAM message  
25 information which causes decryptor, 39K, to cease decrypting and causes microcomputer, 205, to cease loading information at main RAM if the decrypted information of the last signal word of the information segment of said first message contains MOVE bit information (which MOVE bit information  
30 causes EOFS valve, 39H, automatically to transfer inputted information of said word).

Subsequently, in the fashion described in the following twelve paragraphs, receiving the eleventh and last EOFS WORD of said end of file signal causes the apparatus of  
35 the subscriber station of Fig. 3 to load decrypted

2/5

information of the last signal word of the information segment of said first message at main RAM if said decrypted information contains no MOVE bit information and cease loading; to terminate the process of decrypting at decryptor, 5 39K; to execute the program instruction set information loaded at said main RAM as a machine language program, thereby causing the events described in the thirteenth paragraph hereinafter (which begins, "As described in "One Combined Medium" above, running ... "); and to commence 10 waiting to receive from EOFs valve, 39F, the header information of a subsequent SPAM message.

Receiving the eleventh and last EOFs WORD of said end of file signal at EOFs valve, 39F, causes said valve, 39F, to transmit an interrupt signal of EOFs-signal-detected 15 information to control processor, 39J, and to commence waiting for a control instruction from said processor, 39J.

Receiving said interrupt signal causes control processor, 39J, to determine, in a predetermined fashion, a match between information that identifies the EOFs valve that 20 transmitted said signal and the aforementioned from-39F information at the aforementioned SPAM-primary-input-source register memory. Said match causes control processor, 39J, automatically to execute that particular portion of said decrypt-process-and-meter-current-01-or-11-header-message 25 instructions that begins with the instruction that is located at the particular reentry-address of the reentry-address information at the aforementioned SPAM-address-of-next-instruction-upon-primary-interrupt register memory.

Automatically, the instructions of said portion cause control 30 processor, 39J, to transmit to controller, 20, of signal processor, 200, via control information transmission means, a particular preprogrammed first-EOFs-signal-detected interrupt signal then particular primary-end-of-file-signal-detected information and one instance of the aforementioned 35 at-39J information. Receiving said interrupt signal of EOFs-

216

signal-detected information causes control processor, 39J, then to cause matrix switch, 39I, to cease transferring information from EOFs valve, 39F, to decryptor, 39K.

Receiving first-EOFs-signal-detected said interrupt  
5 signal and information causes controller, 20, to execute particular ones of the aforementioned decrypt-with-Z-at-39K and decrypt-a-01-or-11-header-message instructions. Automatically, said ones cause controller, 20, to transmit a particular interrogate-message-end instruction to decryptor,  
10 39K. Said instruction causes decryptor, 39K, in a predetermined fashion and after transferring the aforementioned decrypted information of the last signal word of the information segment of said first message, to transmit particular decryption-complete information to controller, 20,  
15 which information includes particular last-word information that is the binary image of said decrypted information of the last signal word.

Receiving said decryption-complete information causes controller, 20, to execute particular preprogrammed  
20 end-01-or-11-message-decryption instructions that cause controller, 20, to compare said last-word information to preprogrammed information of one EOFs WORD. Resulting in a match, under control of said instructions, causes controller, 20, automatically to transmit a particular transmit-padding-  
25 bits instruction to decryptor, 39K, that decryptor, 39K, has capacity to respond to in a predetermined fashion, which instruction causes decryptor, 39K, to transfer one signal word of padding bits to buffer, 39G, causing said buffer, 39G, automatically to input said word of padding bits to EOFs  
30 valve, 39H. (If the decrypted information of the last signal word of the information segment of said first message contains no MOVE bit information--in other words, if said word is an EOFs WORD--receiving said information causes EOFs valve, 39H, to transfer previously inputted information of  
35 said last word, via matrix switch, 39I, to microcomputer,

217

205, which causes microcomputer, 205, to load said information at particular main RAM.) Then said end-01-or-11-message-decryption instructions cause controller, 20, to cause decryptor, 39K, to discard said key information of decryption key Z, to cease decrypting inputted information and to commence transferring all inputted information to buffer, 39G, without alteration. Next said instructions cause controller, 20, to transmit a particular preprogrammed transmit-EOF-Signal-and-continue instruction to control processor, 39J. In so doing, controller, 20, completes said end-01-or-11-message-decryption instructions, said decrypt-a-01-or-11-header-message instructions and said decrypt-with-Z-at-39K instructions and commences processing in the conventional fashion.

Receiving said transmit-EOF-Signal-and-continue instruction causes control processor, 39J, in a predetermined fashion, to transmit the aforementioned transmit-and-wait instruction to EOFs valve, 39F, then to execute particular instructions of the process portion of said decrypt-process-and-meter-current-01-or-11-header-message instructions. Automatically said instructions cause control processor, 39J, to place "0" at the aforementioned SPAM-Flag-at-secondary-control-level memory signifying that control processor, 39J, is operating at the secondary control level and to commence executing control instructions beginning with that instruction whose particular address/location is the address/location of the information at the aforementioned SPAM-next-secondary-instruction-address memory. Automatically, control processor, 39J, executes particular instructions prior to commencing to wait, compares the information at SPAM-Flag-monitor-info memory with particular preprogrammed "0" information, and no match results. Not resulting in a match causes control processor, 39J, automatically to skip collect-monitor-info instructions and commence waiting for interrupt information of the end of file

2/8

signal.

Receiving said transmit-and-wait instruction causes EOFS valve, 39F, to transfer sequentially eleven instances of EOFS WORD information--that is, one complete end of file  
5 signal--via switch, 39I, to decryptor, 39K; to set the information at the EOFS WORD Counter of said valve, 39F, to zero; to transmit the aforementioned complete-and-waiting information to said control processor, 39J, as an interrupt  
10 signal; and to commence waiting for a control instruction from control processor, 39J, before processing next inputted information.

Receiving said eleven instances of EOFS WORD information causes decryptor, 39K, to transfer said information, without alteration, via buffer, 39G, to EOFS  
15 valve, 39H.

Receiving said information--more precisely, receiving the eleventh instance of an EOFS WORD in said information--causes EOFS valve, 39H, to transmit an interrupt signal of EOFS-signal-detected information to control processor, 39J,  
20 and to commence waiting for a control instruction from said processor, 39J.

Receiving said interrupt signal causes control processor, 39J, to determine, in a predetermined fashion, that the EOFS valve that transmitted said signal is the valve  
25 identified by the aforementioned from-39H information at the aforementioned SPAM-secondary-input-source memory. Said determining causes control processor, 39J, automatically to jump to and execute that particular portion of said load-run-and-code instructions that begins with the instruction that  
30 is located at the particular reentry-address of the reentry-address information at the aforementioned SPAM-address-of-next-instruction-upon-secondary-interrupt memory. Said particular portion is the run portion of said load-run-and-code instructions. Automatically, the instructions of said  
35 portion cause control processor, 39J, to cause matrix switch,

219

39I, to cease transferring information from EOFS valve, 39H, to the CPU of microcomputer, 205, and to commence transferring information from control processor, 39J, to said CPU; to transmit a control instruction to said CPU that 5 causes microcomputer, 205, to cease loading information at said main RAM and execute the information so loaded as so-called "machine executable code" of one so-called "job"; to cause matrix switch, 39I, to cease transferring information from control processor, 39J, to said CPU; then to transmit the 10 aforementioned discard-and-wait instruction, via control transmission means, to EOFS valve, 39H, (causing said valve, 39H, to set the information at said EOFS WORD Counter to "00000000", to transmit the aforementioned complete-and-waiting information to control processor, 39J, as a second 15 interrupt signal, then to commence waiting for a further control instruction from control processor, 39J); and finally, to determine that the information at the aforementioned SPAM-Flag-at-secondary-control-level memory matches particular preprogrammed "0" information and, 20 accordingly, to place "1" at the aforementioned SPAM-Flag-secondary-level-2nd-step-incomplete memory which information indicates that control processor, 39J, has completed the instructions of said run portion. In so doing, control processor, 39J, completes the instructions of said run 25 portion.

Automatically said load-run-and-code instructions cause control processor, 39J, to compare the information at the aforementioned SPAM-Flag-secondary-level-3rd-step-incomplete memory with particular preprogrammed information 30 that is "1". No match results which signifies that control processor, 39J, has already completed the code portion of said load-run-and-code instructions. Not resulting in a match causes control processor, 39J, to complete said load-run-and-code instructions, to place "1" at the aforementioned 35 SPAM-Flag-secondary-level-incomplete register memory

220

signifying completion of the secondary level control functions, to place "1" at the aforementioned SPAM-Flag-at-secondary-control-level register memory, and to commence executing control instructions beginning with that  
5 instruction whose particular address/location is the address/location of the information at the aforementioned SPAM-next-primary-instruction-address memory.

Automatically, the particular instructions that begin at said address/location cause control processor, 39J, to  
10 execute particular end-process-portion-? instructions of said decrypt-process-and-meter-current-01-or-11-header-message instructions. Under control of said end-process-portion-? instructions, control processor, 39J, determines that the information at said SPAM-Flag-secondary-level-incomplete  
15 register memory matches a particular preprogrammed "1"; places "1" at the aforementioned SPAM-Flag-primary-level-2nd-step-incomplete register memory, signifying completion of the process portion of said decrypt-process-and-meter-current-01-or-11-header-message instructions; determines that the  
20 information at the aforementioned SPAM-Flag-primary-level-3rd-step-incomplete register memory matches a particular preprogrammed "1", signifying the completion of the meter portion of said decrypt-process-and-meter-current-01-or-11-header-message instructions; and completes execution of said  
25 decrypt-process-and-meter-current-01-or-11-header-message instructions.

Completing the controlled functions of said first message causes control processor, 39J, automatically to prepare to receive the next SPAM message. Automatically,  
30 control processor, 39J, compares the information at said SPAM-header memory to particular preprogrammed cause-retention-of-exec information that is "01". A match results which causes control processor, 39J, to compare the information at the aforementioned SPAM-Flag-executing-  
35 secondary-command register memory to particular preprogrammed

221

information that is "0". A match results which signifies that control processor, 39J, is executing control functions invoked by information of a secondary level execution segment. Accordingly, said match causes control processor, 5 39J to place information of the information at said SPAM-exec memory at the aforementioned SPAM-last-secondary-01-header-exec register memory (rather than at SPAM-last-01-header-exec register memory). Being preprogrammed to collect monitor information, control processor, 39J, automatically compares 10 the information at said SPAM-Flag-monitor-info memory with particular preprogrammed "0" information. No match results which indicates that control processor, 39J, has transferred monitor information in respect to said first message. Then, automatically, control processor, 39J, causes all apparatus 15 of control processor, 39J, to delete from memory all information of said first message except information at said SPAM-first-precondition, SPAM-last-01-header-exec, and SPAM-last-secondary-01-header-exec memories. Finally, control processor, 39J, causes EOFs valves, 39F and 39H, to commence 20 processing inputted signal words, in their preprogrammed detecting fashions, and outputting information to matrix switch, 39I; causes matrix switch, 39I, to commence transferring information from the EOFs valve identified by the information at the aforementioned SPAM-primary-input-source register memory, which is EOFs valve, 39F, to control 25 processor, 39J; and commences waiting to receive information of a subsequent SPAM header from matrix switch, 39I.

As described in "One Combined Medium" above, running said program instruction set causes microcomputer, 205, (and 30 URS microcomputers, 205, at other subscriber stations) to place appropriate Fig. 1A image information at particular video RAM then to transfer particular-number-of-overlay-completed information and instructions to control processor, 39J. Receiving said information and instructions causes 35 control processor, 39J, to place the number "00000001" at the

222

aforementioned SPAM-second-precondition register memory, signifying that said image information represents the first overlay of its associated video program.

Receiving said 1st meter & monitor information (#4) causes buffer/comparator, 14, automatically to compare the information, in said 1st information, of the header information that identifies a transmission of meter information to particular preprogrammed header-identification-@14 information. A match results with particular meter-identification information which causes buffer/comparator, 14, to select information of particular predetermined bit locations (which locations contain the information of the meter instruction field of said 1st meter & monitor information (#4)) and to compare said selected information to preprogrammed metering-instruction-comparison information. (Matches with particular metering-instruction-comparison information invoke simple metering processes that buffer/comparator, 14, has capacity to perform by itself). No match results (which signifies that the meter processing caused by the information said field is too complex to occur under control of buffer/comparator, 14, alone). Not resulting in a match causes buffer/comparator, 14, automatically to transmit to controller, 20, particular preprogrammed instruct-to-meter information then said selected information (which the meter instruction information of said first message).

Receiving said information causes controller, 20, to compare said meter instruction information to preprogrammed instruct-to-meter-@20 information and to determine that said information matches particular 1-2-3-meter information that invokes three particular sets of instructions preprogrammed at controller, 20. The first set initiates assembly at buffer/comparator, 14, of a first particular meter record that is based on the information, in one meter-monitor field of the first message, of the program unit information of said

223

first command. Assembly of said record enables a particular remote metering station to account for the use of the information of said "Wall Street Week" program and bill subscribers who use said information. The second set causes  
5 assembly at buffer/comparator, 14, of a second particular meter record that is based on the information, in a second meter-monitor field, of the supplier of the program instruction set that follows said first command. The capacity for a given command to cause the assembly of more  
10 than one record enables separate ownership properties that are used jointly in a given instance of SPAM information to be accounted for separately. For example, the copyright owner of said "Wall Street Week" program (who owns the Fig. 1B image) and said supplier (whose information generates the  
15 Fig. 1A image) may be different parties. Said second record enables said remote station (or alternatively, a separate remote metering station) to account for use of said program set separately from the accounting of said "Wall Street Week" program and to charge subscribers separately. The third set  
20 causes the recording at recorder, 16, of said second meter record.

Said match causes controller, 20, to execute said instructions. Under control of said first set, controller, 20, initiates assembly of said first meter record  
25 by selecting and placing at particular record locations at buffer/comparator, 14, particular record format information, then program unit information from a particular meter-monitor field of said 1st meter & monitor information (#4), origin of transmission information from a second field, date and time  
30 of transmission information from a third field, decryption key information from the decryption mark of said 1st meter & monitor information (#4), and finally date and time of processing information from clock, 18.

In its preprogrammed fashion, when said first  
35 specified set is completed, controller, 20, executes said

224

second specified set which causes controller, 20, to assemble said second record. Under control of said second set, controller, 20, places at a particular second record locations at buffer/comparator, 14, particular record format information, then information of the supplier of said program instruction set from a particular meter-monitor field of 1st meter & monitor information (#4), program unit information from a second field, origin of transmission information from a third field, date and time of transmission information from a fourth field, and finally date and time of processing information from clock, 18.

When said second set is completed, controller, 20, executes said third specified set which causes controller, 20, to cause buffer/comparator, 14, to transfer said second meter record to recorder, 16, in a predetermined fashion then discard all information of said record from its memory and to cause recorder, 16, to process and record said transferred meter record in its preprogrammed fashion.

Buffer/comparator, 14, and controller, 20, are preprogrammed to process monitor information, and completing the metering functions invoked by said 1-2-3-meter information causes controller, 20, to cause buffer/comparator, 14, to execute its preprogrammed automatic monitoring functions. These functions proceed in the same fashion that applied to the 1st monitor information (#3). Buffer/comparator, 14, determines that the source mark of said 1st meter & monitor information (#4) matches source information associated with the monitor record of the prior programming displayed at monitor, 202M, but that the program unit information of said 1st meter & monitor information (#4) does not match the program unit information of said monitor record. Accordingly, buffer/comparator, 14, causes the apparatus of signal processor, 200, to record said monitor record at recorder, 16, and to replace said monitor record at buffer/comparator, 14, with a new monitor record based on the

225

information of the 1st meter & monitor information (#4). When buffer/comparator, 14, completes said monitoring functions, buffer/comparator, 14, deletes all unrecorded information of said 1st meter & monitor information (#4) and 5 commences waiting for the next instance of inputted information.

The content of the 1st meter & monitor information (#4) causes controller, 20, to organize the information of said new monitor record in a particular fashion that differs, 10 in one respect, from the new monitor record generated in the third example by the 1st monitor information (#3). Unlike the first combining synch command in the third example, the first combining synch command in the fourth example must be decrypted, and the 1st meter & monitor information (#4) 15 includes a decryption mark. Thus the new monitor record generated by the 1st meter & monitor information (#4) includes decryption key information, not included in the new monitor record generated by the 1st monitor information (#3), and record format field information that reflects the 20 presence of said decryption field information.

#### OPERATING S. P. SYSTEMS ... EXAMPLE #4 (SECOND MESSAGE)

With one exception, the information of the second message of example #4 is identical to the information of the 25 second message of example #2. The meter instruction information the second message of example #4 instruct subscriber station apparatus to perform certain meter operations, described more fully below, that are not performed in example #2. In all other respects the second 30 message of example #4 is identical to the second message of example #2 and is encrypted, embedded, and transmitted at the "Wall Street Week" program originating studio just as in example #2.

But a significant difference exists between examples 35 #2 and #4. Unlike example #2 wherein Fig. 1A image

226

information exists at all URS microcomputers, 205, Fig. 1A image information exists in example #4 only at those subscriber stations where the encrypted information of the first message has been decrypted, causing the apparatus of 5 said stations to load and execute program instruction set information at the microcomputers, 205. Only at said stations does "program unit identification code" information of said "Wall Street Week" program exist at the SPAM-first-precondition register memories of the control processors, 10 39J. Only at said subscriber stations can the second combining synch command cause the display of Fig. 1C information.

Receiving said second message causes the apparatus of the station of Fig. 3 (and other stations that are configured 15 and preprogrammed like the station of Fig. 3), in the following fashion, to decrypt the encrypted portions of said message, to execute the controlled functions of the decrypted information of said message; and to record meter information and monitor information relating to said message.

20 (Simultaneously, receiving said message causes other stations that are configured and/or preprogrammed differently from the station of Fig. 3 to respond, automatically, in fashions that differ from the fashion of the station of Fig. 3 in ways that are described below parenthetically.)

25 When divider, 4, commences transferring the embedded information of said second message to decoder, 203, the binary SPAM information of said message is received at decoder, 203; detected at detector, 34; checked and corrected, as necessary, at processor, 39B; converted into 30 locally usable binary information at processor, 39D; and processed for end of file signal information at EOFs valve, 39F. Receiving the SPAM message information of said message causes EOFs valve, 39F, to transfer said information, via matrix switch, 39I, to control processor, 39J, as fast as 35 control processor, 39J, is prepared to receive said

-227-

information.

Receiving said information causes control processor, 39J, to record the smallest number of signal words that can contain H bits at SPAM-input-signal memory; to select  
5 information of the first H bits at said memory; to record said information at SPAM-header memory; to compare the information at said SPAM-header memory with the aforementioned invoke-monitor-processing information, determine a match with particular preprogrammed "00"  
10 information, and enter "0" at the aforementioned SPAM-Flag-monitor-info register memory; to record additional SPAM signal words at said SPAM-input-signal memory until the total quantity of SPAM signal words recorded at said memory equals the smallest number of signal words that can contain H+X  
15 bits; to record information of the first X bits of information at said SPAM-input-signal memory immediately after the first H bits at said SPAM-exec memory; to compare the information at said memory with the aforementioned controlled-function-invoking information and determine a  
20 match with particular preprogrammed this-message-addressed-to-200 information; and to execute the aforementioned transfer-header-and-exec-seg-info-to-200 instructions.

Executing said instructions causes control processor, 39J, to transfer to controller, 20, of signal processor, 200,  
25 via control information transmission means, an interrupt signal, the aforementioned process-this-message information and at-39J information, and information of the header and execution segment of said second message.

Receiving said interrupt signal and information causes  
30 controller, 20, in a predetermined fashion, to cease a processing task that is unrelated to the processing of said second message; to compare said information of the execution segment to the aforementioned controlled-function-invoking-@200 information and determine a match with particular  
35 decrypt-with-key-J information; to execute particular

228

preprogrammed decrypt-with-J-at-39K instructions; to select and transfer key information of J to decryptor, 39K; to compare said information of the header to the aforementioned header-identification-@200 information and determine a match  
5 with particular "00" header information; to execute particular preprogrammed decrypt-a-00-header-message-at-39K instructions; to transmit a particular preprogrammed process-  
and-transmit-info-of-MMS-L instruction, via control  
transmission means, to control processor, 39J; then, in a  
10 predetermined fashion, to commence an unrelated processing task.

Receiving said last named instruction causes control processor, 39J, to execute particular preprogrammed process-length-token-and-transmit-MMS-L instructions; to record  
15 additional SPAM signal words at said SPAM-input-signal memory until the quantity of SPAM words recorded at said memory is the smallest number of words that can contain H+X+L bits; to select information of the first L bits at said memory immediately after the first H+X bits; to determine that said  
20 information matches Y-token information; to select y-bits information associated with said Y-token information and record said y-bits information at said SPAM-length-info memory (thereby placing at said memory information of the number of encrypted meter-monitor segment bits in said second  
25 message after the last bit of length token--that is, the numeric value of MMS-L); and to transmit to controller, 20, via control transmission means, an interrupt signal, the aforementioned at-39J information, information of said numeric value of MMS-L.

30 Receiving said interrupt signal, at-39J information, information of MMS-L causes controller, 20, in the aforementioned predetermined fashion, to cease an unrelated processing task; to execute, in a predetermined fashion, particular preprogrammed ones of the aforementioned decrypt-  
35 a-00-header-message-at-39K instructions; to transmit to

229

decryptor, 39K, particular decrypt-a-00-header-message instructions (which instructions include information of MMS-L); to transmit to control processor, 39J, a particular decrypt-process-and-meter-a-00-message instruction and  
5 particular decryption mark information of key J; then, in a predetermined fashion, to commence an unrelated processing task.

Receiving said last named instruction and mark information causes control processor, 39J, to record said  
10 mark information at the aforementioned SPAM-decryption-mark register memory; to enter "1" at the aforementioned SPAM-Flag-monitor-info register memory; to place particular from-39F information at the aforementioned SPAM-primary-input-source register memory; and to execute particular  
15 preprogrammed decrypt-process-and-meter-current-00-header-message instructions.

Executing said instructions causes control processor, 39J, first, to receive all remaining command information and padding bits in said second message in the following fashion.  
20 Said instructions cause control processor, 39J, to add H+X+L to the information of y-bits at the aforementioned SPAM-length-info memory; to determine a particular number of signal words to receive from EOFs valve, 39F; to receive and record said words at said SPAM-input-signal memory  
25 immediately following SPAM signal word previously recorded at said memory; if the command information of said message fills a whole number of signal words, to receive one additional signal word, compare the information of said word to information of one EOFs WORD, record said word at said SPAM-  
30 input-signal memory immediately following the last SPAM signal word recorded at said memory, and receive and record the information of one more SPAM signal word at said SPAM-input-signal memory immediately following the last SPAM  
signal word recorded at said memory if said one additional  
35 signal word has matched said EOFs WORD information; and to

230

cease accepting SPAM signal information from EOFs valve, 39F.

Executing said decrypt-process-and-meter-current-00-header-message instructions causes control processor, 39J, then, to transfer to decryptor, 39K, the SPAM information of  
5 said second message in the following fashion. Said instructions cause control processor, 39J, to cause matrix switch, 39I, to cease transferring information from EOFs valve, 39F, to control processor, 39J, and commence transferring information from control processor, 39J, to  
10 decryptor, 39K, and cause control processor, 39J, to transfer all information recorded at said SPAM-input-signal memory of control processor, 39J, which information is complete information of said second message.

Automatically, decryptor, 39K, commences receiving  
15 SPAM signal information.

Executing said decrypt-process-and-meter-current-00-header-message instructions causes control processor, 39J, then, in the following fashion, to prepare to receive the decrypted information of said second message and to execute,  
20 at a secondary control level under primary control of said decrypt-process-and-meter-current-00-header-message instructions, the controlled functions invoked by said decrypted information. Said instructions cause control processor, 39J, to place information of a particular reentry-  
25 address at the aforementioned SPAM-next-primary-instruction-address register memory; to place information of "0" at the aforementioned SPAM-Flag-primary-level-2nd-step-incomplete register memory and, separately, at SPAM-Flag-primary-level-3rd-step-incomplete register memory; to place information of  
30 "0" at the aforementioned SPAM-Flag-secondary-level-incomplete register memory; to compare the information at said SPAM-Flag-monitor-info memory with particular preprogrammed "0" information and skip all steps of collecting monitor information because no match results; to  
35 cause all apparatus of control processor, 39J, to delete from

231

memory all information of said second message except information at said SPAM-decryption-mark, SPAM-Flag-at-secondary-control-level, SPAM-primary-input-source, SPAM-next-primary-instruction-address register memories; to cause 5 matrix switch, 39I, to cease transferring SPAM message information from control processor, 39J, to decryptor, 39K, and commence transferring SPAM message information from EOFs valve, 39H, to control processor, 39J; to place information of "0" at the aforementioned SPAM-Flag-executing-secondary- 10 command register memory; to place information of "0" at the aforementioned SPAM-Flag-at-secondary-level register memory; and to commence waiting to receive information of a subsequent SPAM header from said switch, 39I.

Receiving from controller, 20, the aforementioned key 15 information of J and decrypt-a-00-header-message instructions (that include information of MMS-L) and from matrix switch, 39I, the aforementioned transferred SPAM message information that is complete information of said second message causes decryptor, 39K, to transfer the first H bits of said SPAM 20 information to buffer, 39G, without decrypting or altering said bits in any fashion; to decrypt and transfer the next X bits of said information; to transfer the next L bits without decrypting or altering said bits; to decrypt and transfer the next MMS-L bits; and finally, to transfer any bits remaining 25 after the last of said MMS-L bits without decrypting or altering said bits remaining. In so doing, decryptor, 39K, inputs complete unencrypted information of said second message to buffer, 39G. Said complete unencrypted information is identical to the SPAM message information that 30 decryptor, 10, inputs to controller, 12, in example #2.

Receiving said complete unencrypted information causes buffer, 39G, automatically to buffer said information and input said information to EOFs valve, 39H, and causes EOFs valve, 39H, to transfer said information, via matrix switch, 35 39I, to control processor, 39J, as fast as control processor,

232

39J, is prepared to receive said information.

Receiving said information causes control processor, 39J, to record the smallest number of signal words that can contain H bits at SPAM-input-signal memory; to select  
5 information of the first H bits at said memory; to record said information at SPAM-header memory; to compare the information at said SPAM-header memory with the  
aforementioned invoke-monitor-processing information, determine a match with particular preprogrammed "00"  
10 information, and enter "0" at the aforementioned SPAM-Flag-monitor-info register memory; to record additional SPAM  
signal words at said SPAM-input-signal memory until the total quantity of SPAM signal words recorded at said memory equals  
the smallest number of signal words that can contain H+X  
15 bits; to record information of the first X bits of information at said SPAM-input-signal memory immediately  
after the first H bits at said SPAM-exec memory; to compare the information at said memory with the aforementioned  
controlled-function-invoking information and determine a  
20 match with the aforementioned execute-conditional-overlay-at-205 information; and to execute the aforementioned  
conditional-overlay-at-205 instructions.

Executing said instructions causes control processor, 39J, first, to receive all remaining command information and  
25 padding bits in said second message in the following fashion. Said instructions cause control processor, 39J, to record  
additional SPAM signal words at said SPAM-input-signal memory until the quantity of SPAM words recorded at said memory is  
the smallest number of words that can contain H+X+L bits; to  
30 select information of the first L bits at said memory immediately after the first H+X bits; to determine that said  
information matches Y-token information; to select y-bits information that is information of the numeric value of MMS-L  
and record said information at said SPAM-length-info memory;  
35 add H+X+L to the information said memory; to determine a

233

particular number of signal words to receive from EOFS valve, 39H; to receive and record said words at said SPAM-input-signal memory immediately following SPAM signal word previously recorded at said memory; if the command

5 information of said message fills a whole number of signal words, to receive one additional signal word, compare the information of said word to information of one EOFS WORD, record said word at said SPAM-input-signal memory immediately following the last SPAM signal word recorded at said memory,

10 and receive and record the information of one more SPAM signal word at said SPAM-input-signal memory immediately following the last SPAM signal word recorded at said memory if said one additional signal word has matched said EOFS WORD information; and to cease accepting SPAM signal information.

15 By receiving all command information and padding bits in said second message, control processor, 39J, receives all of the unencrypted complete information of said second message. Accordingly, the next signal word to be transferred by said valve, 39H, will be the first word of a subsequent

20 message inputted to buffer, 39G.

Executing said conditional-overlay-at-205 instructions causes control processor, 39J, then, in the following fashion, to locate information of the the unique "program unit identification code" that identifies the program unit of

25 said "Wall Street Week" program and determine that said information matches the information at the aforementioned SPAM-first-precondition register memory. Said instructions cause control processor, 39J, to select information of the bits of the meter-monitor format field in said first message;

30 to compare said information with format-specification information; to determine a match with particular D-format information; to place at the aforementioned SPAM-mm-format memory a particular D-offset-address number that is different from the aforementioned A-, B-, and C-offset-address numbers;

35 to execute the aforementioned locate-program-unit

234

instructions and locate the program unit field in the meter-monitor information of said second message in the fashion described above; to select binary information of a particular number of contiguous bit locations at said SPAM-input-signal  
5 memory that begin at a particular number of bit locations after the first bit location at said memory (which binary information is said information of the the unique "program unit identification code"); and to compare said binary information to the information at the aforementioned SPAM-  
10 first-precondition register memory, causing a match to result.

(At those subscriber stations where the information of the program unit field in the meter-monitor information of said second message fails to match information at SPAM-first-  
15 precondition register memory--including all stations that are preprogrammed with decryption key information of J but not with decryption key information of Z--particular first-condition-test-failed instructions of said conditional-overlay-at-205 instructions cause the control processors,  
20 39J, of said stations to enter "0" at each of the aforementioned SPAM-Flag-first-condition-failed and SPAM-Flag-do-not-meter register memories, which memories are each normally "1"; to cause all SPAM information at the main and video RAMs of the microcomputers, 205, of said stations to be  
25 cleared; and to complete all conditional-overlay-at-205 instructions and, in so doing, to complete all controlled functions invoked by said second message at the secondary control level.)

So resulting in a match, under control of the  
30 conditional-overlay-at-205 instructions at the station of Fig. 3, causes control processor, 39J, then, to execute the aforementioned locate-overlay-number instructions and locate the overlay number field in the meter-monitor information of said second message in the fashion described above; to select  
35 binary information of a particular number of contiguous bit

235

locations at said SPAM-input-signal memory that begin at a particular number of bit locations after the first bit location at said memory (which binary information is the information of said overlay number field); and to compare  
5 said binary information to the information at the aforementioned SPAM-second-precondition register memory, causing a match to result.

(At those subscriber stations where the information of the overlay number fails to match information at SPAM-second-  
10 precondition memory, particular second-condition-test-failed instructions of said conditional-overlay-at-205 instructions cause the control processors, 39J, of said stations to interrupt the operation of the CPUs of the microcomputers, 205, of said stations; to cause said microcomputers, 205, to  
15 restore efficient operation in a fashion described more fully below; to enter "0" at the aforementioned SPAM-Flag-second-condition-failed register memory, which memories is normally "1"; and to complete all conditional-overlay-at-205 instructions and controlled functions invoked by said second  
20 message at the secondary control level.)

So resulting in a match, under control of said conditional-overlay-at-205 instructions at the station of Fig. 3, causes control processor, 39J, (and control  
processors, 39J, at other subscriber stations where matches  
25 with information at SPAM-second-precondition memory result) to cause matrix switch, 39I, to cease transferring information from EOFS valve, 39H, to control processor, 39J, and commence transferring information from control processor, 39J, to the PC-MicroKey System of microcomputer, 205; to  
30 transmit the instruction, "GRAPHICS ON", to said PC-MicroKey System; to cause matrix switch, 39I, to cease transferring information from control processor, 39J, to said PC-MicroKey System; and to complete all conditional-overlay-at-205 instructions and controlled functions invoked by said second  
35 message at the secondary control level.

236

Transmitting the instruction, "GRAPHICS ON", to the PC-MicroKey System of the subscriber station of Fig. 3 (and transmitting "GRAPHICS ON" to other PC-MicroKey Systems at other subscriber stations where the program instruction set 5 of the first message has been run at a microcomputer, 205, and where said second message causes "GRAPHICS ON" to be transmitted) causes said PC-MicroKey System to combine the programming of Fig. 1A and of Fig. 1B and transmit the combined programming to monitor, 202M, where Fig. 1C is 10 displayed.

Completing all conditional-overlay-at-205 instructions and controlled functions invoked at the secondary control level causes control processor, 39J, (and causes control processors, 39J, at other stations) to execute conventional 15 control-function-complete instructions and compare the information at the aforementioned SPAM-Flag-at-secondary-control-level memory to particular "0" information. A match results.

Resulting in a match, under control of said 20 instructions causes control processor, 39J, to place "1" at the aforementioned SPAM-Flag-secondary-level-incomplete memory, to place "1" at said SPAM-Flag-at-secondary-control-level memory, and to commence executing control instructions beginning with that instruction whose particular 25 address/location is the address/location of the information at the aforementioned SPAM-next-primary-instruction-address memory.

Automatically, the particular instructions that begin at said address/location cause control processor, 39J, to 30 execute the particular end-process-portion-? instructions of said decrypt-process-and-meter-current-00-header-message instructions. Under control of said end-process-portion-? instructions, control processor, 39J, determines that the information at said SPAM-Flag-secondary-level-incomplete 35 memory matches a particular preprogrammed "1"; places "1" at

237

the aforementioned SPAM-Flag-primary-level-2nd-step-incomplete register memory; determines that a comparison of the information at the aforementioned SPAM-Flag-primary-level-3rd-step-incomplete register memory with a particular  
5 preprogrammed "1" does not result in a match, signifying that the meter portion of said decrypt-process-and-meter-current-00-header-message instructions remains uncompleted.

Not resulting in a match causes control processor, 39J, under control of said decrypt-process-and-meter-current-  
10 00-header-message instructions, to execute the meter portion of said instructions. Under control of the instructions of said portion, control processor, 39J, compares the information at the aforementioned SPAM-Flag-do-not-meter register memory to particular preprogrammed information of  
15 "0". No match results.

(At those subscriber stations where the aforementioned first-condition-test-failed instructions caused "0" to be entered at the SPAM-Flag-do-not-meter memories of said stations, matches result when the information at said  
20 memories is compared to "0". Said matches cause the control processors, 39J, of said stations to complete the decrypt-process-and-meter-current-00-header-message instructions of said stations and all controlled functions invoked by said second message immediately, without transferring any meter  
25 information to the buffer/comparators, 14, of said stations and, at particular selected ones of said stations, without entering "1" at the SPAM-Flag-monitor-info memories. Said selected stations are stations that are preprogrammed to collect monitor information.)

30 Not resulting in a match, under control said meter portion at the station of Fig. 3, causes control processor, 39J, to compare the information at the aforementioned SPAM-Flag-second-condition-failed register memory to particular preprogrammed information of "1". A match results.

35 (At such other stations where no matches result, not

238

resulting in a match, under control of said instructions, causes the control processor, 39J, of each one of said other stations, to execute particular second-precondition-failed-meter instructions of said meter portion. Automatically, 5 said instructions cause control processor, 39J, to transfer to the buffer/comparator, 14, of said one, particular header information that identifies a transmission of meter information at a station where inefficient operation of a microcomputer, 205, prevented combining; then the decoder-203 10 source mark of the decoder, 203, of said station; then information of the decryption mark of key J information recorded at SPAM-decryption-mark register memory of said station; then all of the received binary information of said second message that is recorded at said SPAM-input-signal 15 memory of said station. Said transmitted information is called, hereinafter, the "2nd meter-monitor information--second precondition failed--(#4)." Then said instructions cause control processor, 39J, to place "1" at said SPAM-Flag-second-condition-failed memory and continue the regular 20 instructions of said portion.)

Resulting in a match, under control said meter portion at the station of Fig. 3, causes control processor, 39J, to cause matrix switch, 39I, to commence transferring information from control processor, 39J, to 25 buffer/comparator, 14, of signal processor, 200; to transfer the aforementioned header information that identifies a conventional transmission of meter information then the aforementioned decoder-203 source mark then information of the information recorded at said SPAM-decryption-mark 30 register memory, which is the decryption mark of key J, then all of the received binary information of said second message that is recorded at said SPAM-input-signal memory; then to cause matrix switch, 39I, to cease transferring information from control processor, 39J, to said buffer/comparator, 14. 35 (Said received information is complete information of the

239

second combining synch command of example #4, and said information that is transmitted to buffer/comparator, 14, is called, hereinafter, the "2nd meter-monitor information (#4).") Then the instructions of said portion cause control processor, 39J, to enter "1" at said SPAM-Flag-monitor-info memory; to enter "1" at the aforementioned SPAM-Flag-primary-level-3rd-step-incomplete register memory; and to determine that a comparison of the information at the aforementioned SPAM-Flag-primary-level-2nd-step-incomplete register memory with a particular preprogrammed "1" results in a match, signifying the completion of the process portion of said decrypt-process-and-meter-current-00-header-message instructions.

Resulting in a match causes control processor, 39J, to complete said decrypt-process-and-meter-current-00-header-message instructions and all controlled functions of said second message.

Completing the controlled functions of said second message causes control processor, 39J, automatically to prepare to receive the next SPAM message. Automatically, control processor, 39J, compares the information at said SPAM-header memory to particular preprogrammed cause-retention-of-exec information that is "01". No match results. Not resulting in a match causes control processor, 39J, to execute particular collect monitor information and to compare the information at said SPAM-Flag-monitor-info memory with particular preprogrammed "0" information. No match results.

(By contrast, matches result at every station that is preprogrammed to collect monitor information where said second message is decrypted but Fig. 1C image information is not displayed because the "program unit identification code" information in said second message fails to match information at SPAM-first-precondition register memory. Said matches cause the control processors, 39J, of said stations to

240

execute the aforementioned collect-monitor-information instructions. Said instructions cause said control processors, 39J, to transfer to the buffer/comparators, 14, particular header information that identifies a transmission  
5 of monitor information at a station where no combining occurred because first precondition program unit information failed to match and which transmission contains decryption mark information, then to transfer the aforementioned decoder-203 source mark information, then information of the  
10 decryption mark of key J information recorded at SPAM-decryption-mark register memory, then all of the received binary information of said second message that is recorded at the SPAM-input-signal memories of said stations. Said information that is transmitted to said buffer/comparators,  
15 14, is called, hereinafter, the "2nd monitor information (#4)." Then said instructions cause said control processors, 39J, to place "1" at said SPAM-Flag-monitor-info memory, at the aforementioned SPAM-Flag-first-condition-failed memory, and at the aforementioned SPAM-Flag-do-not-meter memory and  
20 to continue executing conventional control instructions. Then the conventional control instructions of said stations cause said control processors, 39J, to cause all apparatus of the controllers, 39, to delete from memory all information of said second message and to commence waiting to receive  
25 information of a subsequent SPAM header from the matrix switches, 39I.)

Not resulting in a match, at the station of Fig. 3, causes control processor, 39J, to cause all apparatus of controller, 39, to delete from memory all information of said  
30 second message; to cause matrix switch, 39I, to commence transferring information from the EOFs valve identified by the information at the aforementioned SPAM-primary-input-source register memory, which is EOFs valve, 39F, to control processor, 39J; and to commence waiting to receive  
35 information of a subsequent SPAM header from matrix switch,

241

39I.

Receiving said 2nd meter & monitor information (#4) causes buffer/comparator, 14, automatically to compare the header information that identifies a transmission of meter information to particular preprogrammed header-identification-@14 information. A match results with the aforementioned meter-identification information, causing buffer/comparator, 14, to select the meter instruction information of the aforementioned particular bit locations of the meter instruction field of said 2nd meter & monitor information (#4) and to compare said selected information to the aforementioned metering-instruction-comparison information. No match results, causing buffer/comparator, 14, automatically to transmit to controller, 20, the aforementioned instruct-to-meter information then said meter instruction information.

Receiving said information causes controller, 20, to compare said meter instruction information to the aforementioned instruct-to-meter-@20 information and to determine that said meter instruction information matches particular preprogrammed update-program-record-&-increment-by-one information that causes controller, 20, to execute particular update-and-increment instructions. Said instructions cause signal processor, 200, not only to add one incrementally to each meter record maintained at buffer/comparator, 14, that is associated with decryption key information of the instance of meter information being processed (which is, substantively, the metering function invoked by the 2nd meter information (#2)) but also to modify the information of the aforementioned first particular meter record, initiated by the 1st meter & monitor information (#4). (The particular metering function invoked by said 2nd meter information (#2) could not modify any of the information of said first particular meter record, even by incrementing by one, because no information of decryption key

24/2

J is associated with said record when the 2nd meter & monitor information (#4) is received at buffer/comparator, 14.)

Executing said update-and-increment instructions causes controller, 20, in a predetermined fashion, to analyze the information of said 2nd meter & monitor information (#4); to place information of the information of the overlay number field in said 2nd information at a particular record field associated with said first particular meter record, signifying the combining of said overlay at the subscriber station of Fig 3; and to place, at the particular record location occupied by record format information, particular new record format information that identifies the new format of said first particular meter record; to compare the decryption mark information in said 2nd meter & monitor information (#4) with the aforementioned decryption-key-comparison information, preprogrammed at buffer/comparator, 14; to determine several matches; to increment by one the meter record, at buffer/comparator, 14, associated with each particular decryption-key-comparison datum that matches the decryption mark of said 2nd meter & monitor information (#4); to discard all information of said 2nd meter & monitor information (#4) from its memory; and to complete said update-and-increment instructions.

Completing the metering functions invoked by said meter instruction information causes controller, 20, to cause buffer/comparator, 14, to execute its preprogrammed automatic monitoring functions. These functions proceed in the fashion that applied to the 2nd monitor information (#3).

The content of the 2nd meter & monitor information (#4) causes onboard controller, 14A, to organize the information of said new monitor record in a particular fashion that differs, in one respect, from the new monitor record generated in the third example by the 2nd monitor information (#3). The 2nd meter & monitor information (#4) includes a decryption mark. The presence of said mark causes

243

causes onboard controller, 14A, to include decryption key information of J, not included in the new monitor record generated by the 1st monitor information (#3), and record format field information that reflects the presence of said 5 decryption field information.

(At each station where the aforementioned 2nd meter & monitor information--second precondition failed--(#4) is transmitted, receiving said 2nd information--failed--(#4) causes the buffer/comparator, 14, of said station 10 automatically to compare the information, in said 2nd information--failed--(#4), of the header that identifies a transmission of meter information at a station where inefficient operation of a microcomputer, 205, prevented combining to the aforementioned header-identification-@14 15 information. A match results with particular second-precondition-failed information, causing buffer/comparator, 14, to select information of the aforementioned particular bit locations that contain the information of the meter instruction field of said 2nd information--failed--(#4) then 20 automatically to transmit to controller, 20, a particular preprogrammed instruct-to-process-info-failed information then said selected information, which is the meter instruction information of said second message. Receiving said information causes controller, 20, in a predetermined 25 fashion, to execute particular preprogrammed increment-by-one-&-record-failed-combining-info information that invokes to particular sets of instructions preprogrammed at controller, 20. The first set causes controller, 20, to cause buffer/comparator, 14, to add one incrementally to each 30 meter record maintained at buffer/comparator, 14, that is associated with decryption key information that matches the decryption mark of said 2nd information--failed--(#4) in the fashion of example #2. Then the second set causes controller, 20, to assemble a record of a failed combining at 35 buffer/comparator, 14; to record said record at recorder, 16,

244

in the fashion of the second and third sets of example #4 (first message); and to complete the metering functions invoked by said increment-by-one-&-record-failed-combining-info information. The content of said record includes  
5 information that identifies said record as information of a combining aborted due to inefficient operation of a subscriber station microcomputer, 205; the unique digital code information capable of identifying the subscriber station of Fig. 3 uniquely, which information is  
10 preprogrammed at controller, 20; and the "program unit identification code" and overlay number information of the meter-monitor segment information of said second message in said 2nd information--failed--(#4). At each station that processes said 2nd information--failed--(#4) and that is  
15 preprogrammed to collect monitor information, completing said metering functions causes the controller, 20, of said station to cause the buffer/comparator, 14, to execute its preprogrammed automatic monitoring functions. These functions proceed in the fashion that applied to the 2nd  
20 meter & monitor information (#4) with particular exceptions. Receiving said 2nd information--failed--(#4) causes the onboard controller, 14A, to add not only decryption key information but also information that combining failed to occur because of inefficient microcomputer operation and that  
25 the combining is of the overlay number of the information of the overlay number field in said 2nd information--failed--(#4).)

(At each station where the aforementioned 2nd monitor information (#4) is transmitted, no 1st meter & monitor  
30 information (#4) transmission occurred; onboard controller, 14A, has not initiated a new monitor record of the "Wall Street Week" program; and the aforementioned record of the prior programming displayed at monitor, 202M, remains at buffer/comparator, 14. Accordingly, receiving said 2nd  
35 monitor information (#4) causes the buffer/comparator, 14, of

245

said station to process information in the fashion of the 1st monitor information (#3). Automatically, said buffer/comparator, 14, determines that the header information in said 2nd monitor information (#4) matches particular

5 preprogrammed monitored-instruction-not-fulfilled information which causes buffer/comparator, 14, to input said 2nd monitor information (#4) to onboard controller, 14A. Receiving said 2nd monitor information (#4) causes onboard controller, 14A, to execute the aforementioned process-monitor-info

10 instructions; to determine that the "program unit identification code" in said 2nd monitor information (#4) does not match the "program unit identification code" information in said record of prior programming; to cause signal processor, 200, to record said said record of prior

15 programming at recorder, 16; to initiate a new monitor record that reflects the new "Wall Street Week" programming; and finally, to discard all unrecorded information of said 2nd monitor information (#4) and commence waiting for the next inputted instance of monitor information. The header

20 information of the 2nd monitor information (#4) causes signal processor, 200, to assemble said new monitor record in the particular format of a combined video/computer medium transmission at a station where no combining occurred because first precondition program unit information failed to match

25 and to include a particular record format field within said format identifying the format of said record. From the meter-monitor segment of said 2nd monitor information (#4), onboard controller, 14A, selects and records at particular signal record field locations the "program unit

30 identification code" of the "Wall Street Week" program, the overlay number information, and minute of the "Wall Street Week" program transmission within a one month period. And onboard controller, 14A, records in a particular monitor record field location the aforementioned display unit

35 identification code that identifies monitor, 202M, as the

246

display apparatus of said new monitor record and date and time information received from clock, 18.)

OPERATING S. P. SYSTEMS ... EXAMPLE #4 (THIRD MESSAGE)

5           Subsequently, the embedded information of the third message of the "Wall Street Week" program is inputted to decoder, 203. Said information is identical to the embedded information of the third message of examples #1, #2, and #3 and causes the same processing at decoder, 203, that the  
10 information of the third message of example #3 caused. The information of the third message of example #4 causes "GRAPHICS OFF" to be executed at the PC-MicroKey System of the microcomputers, 205, of all subscriber stations tuned to the "Wall Street Week" transmission. But like the third  
15 message of example #2, the third message of example #4 causes combining actually to cease only each selected one of said stations where information of the second message previously caused combining to commence.

          However, example #4 does differ from example #2. In  
20 example #2, the second message causes combining to commence at every selected station where the information of said second message is decrypted; that is, every station preprogrammed with information of decryption key J. But the second message of example #4 causes combining to commence  
25 only at those selected stations where information not only of said second message is decrypted but also where information of the first message of example #4 had been decrypted; that is, only at those stations preprogrammed not only with information of decryption key J but also information of  
30 decryption key Z.

          Thus example #4 illustrates a case where not only does selective processing of the second message enable the third message to have effect only at selected stations without any selective processing of said third message, the selective  
35 processing of the first message enables the third message to

247

have effect only at an even more selective group of stations than would otherwise be the case. Placing the PC-MicroKey Systems of all stations into the "Graphics Off" mode prior to transmitting the first message of example #4 enables the  
5 third message of example #4 in the simplest possible fashion to cause combining to cease only at those stations that are preprogrammed with decryption key information not only of J but also of Z, with all the benefits outlined at the end of example #2.

10 Placing particular so-called "soft switches," one of which exists at each subscriber station, all into one given original position, "off" or "on", then transmitting a command that is processed selectively at selected stations and places said switches at said stations into the opposite position,  
15 "on" of "off", makes it possible to transmit a subsequent command that returns said switches at said selected stations (and only said switches) to said original position without any additional selective processing.

Significant advantages of simplicity and speed are  
20 achieved by devising signal processing apparatus and methods that minimize the need for selective processing. With regard to said third combining synch command, for example, no step of decrypting is required to affect only those stations that are preprogrammed with decryption key J. Accordingly, no  
25 possibility exists that an error in decrypting may occur at one or more of said stations, causing the combining of video RAM information and received video information, at said one or more, not to cease at the proper time and to continue beyond said time (until such time as some subsequent command may execute "GRAPHICS OFF" or clear information from said  
30 video RAM at said stations). Because no time is required for decrypting, no possibility exists that some station may take longer (or shorter) than proper to perform decrypting causing the image of Fig. 1A to be displayed at some monitor, 202M,  
35 longer (or shorter) than proper. Perhaps most important,

248

because no time is required for selective processing of said third command, the time interval that separates the time of embedding said third command at said remote station that originates the "Wall Street Week" program and the time of  
5 ceasing caused by said command at URS microcomputers, 205, can be the shortest possible interval. Making it possible for said time interval to be the shortest possible interval minimizes the chance that an error may occur in the timing of the embedding of said third command at said remote station  
10 causing all URS microcomputers, 205, to cease combining at a time that is other than the proper time.

#### OPERATING SIGNAL PROCESSOR SYSTEMS ... EXAMPLE #5

Example #5 focuses on program unit identification  
15 signals detected at decoders, 30 and 40, of signal processor, 200.

Signal processor, 200, is preprogrammed with information that identifies each cable and over-the-air (hereinafter, "wireless") transmission or frequency in the  
20 locality of the subscriber station of Fig. 3 as well as the standard broadcast and cablecast practices that apply on said transmissions and frequencies. Via a conventional multi-channel cable transmission, in a fashion well known in the art, four channels of conventional television programming and  
25 two conventional FM radio signals are inputted to a first alternate contact of switch, 1, and to mixer, 2. Said television channels are transmitted normally assigned to channels 2, 4, 7, and 13 of the television frequency spectrum. Said radio signals are transmitted on 99.0 MHz and  
30 100.0 MHz of the FM frequency spectrum. Via a conventional television receiving antenna, three conventional wireless television transmissions are inputted to the second alternate contact of switch, 1. Said wireless transmissions are on the frequencies of the television spectrum normally assigned to  
35 channels 5, 9, and 13. In a predetermined fashion,

249

controller, 20, controls oscillator, 6, to sequence local oscillator, 6, in the pattern: cable channel 2, cable channel 4, cable channel 7, cable channel 13, wireless channel 5, wireless channel 9, wireless channel 13, then to repeat said 5 pattern.

In example #5, the "Wall Street Week" combining synch commands are transmitted unencrypted as in the first example, and the "Wall Street Week" program is transmitted on the frequency of channel 13 by a wireless broadcast station whose transmission is retransmitted on the frequency of channel 13 on said cable. Thus a viewer can tune to the "Wall Street Week" program on either wireless channel 13 or cable channel 13. Simultaneously, different programs are transmitted on each of the other television and radio transmissions.

15 Controller, 20, has preprogrammed the RAM associated with the control processor, 39J, of the controller, 39, of decoder, 30, with bit information of a channel mark associated with each transmission of television programming received at decoder, 30. (While wireless channel 13 and 20 cable channel 13 may transmit the same programming, they have different channel marks.) At said RAM, said control processor, 39J, maintains, associated with appropriate channel mark information, monitor information records of the last command containing meter-monitor program identification 25 information inputted via each channel transmission. Said records include program unit identification information. At the outset of the example, no transmission of "Wall Street Week" program unit identification information has yet occurred, and the program unit information associated with 30 the source mark of wireless channel 13 and, separately, with the source mark of cable channel 13 is the unit information of the television programming transmitted immediately before the start of the "Wall Street Week" transmission.

At the outset of example #5, the contact lever of 35 switch, 1, is connected to said first alternate contact of

250

switch, 1, to which is inputted the full spectrum of frequencies transmitted on said cable, and mixer, 3, is set to select the frequency of channel 13. Thus transmissions on cable channel 13 are inputted to decoder, 30. Furthermore, 5 the EOFS valve, 39F, of controller, 39, of decoder, 30, has identified an end of file signal embedded in the inputted channel 13 transmission and is set to receive transfer SPAM message information; the matrix switch, 39I, of said controller, 39, is set to transfer SPAM message information 10 from said EOFS valve, 39F, to said control processor, 39J; and said control processor, 39J is set to receive and process header information of a SPAM message.

Example #5 begins with the embedding and transmitting, at the remote station that originates the "Wall Street Week" 15 broadcast, of the first message of the "Wall Street Week" program which is the message of the first combining synch command. The transmission of said broadcast is received at the remote cable transmission station that transmits the multi-channel cable transmission inputted to signal 20 processor, 200; combined into the full spectrum cable transmission on the frequency of channel 13; and retransmitted. Said cable transmission is inputted via said first alternate contact of switch, 1, and said contact lever to mixer, 3. Mixer, 3, selects the frequency of channel 13 25 and inputs said frequency of interest, at a fixed frequency, to TV signal decoder, 30.

Receiving said frequency of interest causes decoder, 30, (which is shown in greater detail in Fig. 2A and whose controller, 39, is shown in greater detail in Fig 3A) to 30 receive and process the command information of said first message. The inputted frequency of channel 13 is inputted, first, to filter, 31, which filters said input and outputs the one TV channel signal of channel 13 to amplitude demodulator, 32. Demodulator, 32, demodulates said inputted 35 channel signal using standard demodulator techniques and

25/

transfers the demodulated channel signal of said channel 13 to digital detector, 38; line receiver, 33; and audio demodulator, 35. Thereafter, the embedded information of the first combining synch command is caused to be recorded at 5 the SPAM-input-signal register memory of the control processor, 39J, of said decoder, 30, in the same fashion that the embedded information of said message is detected and recorded at decoder, 203, in example #3. Receiving said embedded information causes the binary SPAM information of 10 said first command, with error correcting information, to be detected at detector, 34; checked and corrected, as necessary, at processor, 39B; converted into locally usable binary information at processor, 39D; and recorded at the SPAM-input-signal memory of said control processor, 39J.

15 The control apparatus of decoder, 30, is preprogrammed to process said information as monitor information and local control information. (Hereinafter, said first command may be called the 1st command (#5).) Receiving said first command causes the preprogrammed instructions at the RAM and ROM 20 associated with control processor, 39J, to cause control processor, 39J, to process the information of said command in the following fashion. In a predetermined fashion, control processor, 39J, locates the monitor information that it retains in said RAM associated with the channel mark of cable 25 channel 13 and compares the "program unit identification code" of said first command with the program unit information of said monitor information in RAM. No match results which indicates cable channel 13 is transmitting a new program unit. Not resulting in a match causes said controller, 39, 30 automatically to transfer information of new programming to microcomputer, 205, and to transfer to buffer/comparator, 14, for further processing said monitor information in RAM which is monitor information of the programming transmitted on cable channel 13 prior to the "Wall Street Week" program. 35 Automatically, said control processor, 39J, causes matrix

252

switch, 39I, to cease transferring information from said EOFs valve, 39F, to control processor, 39J, and commence transferring information from control processor, 39J, to buffer/comparator, 8, (to which said matrix switch, 39I, has capacity to transfer information). Automatically said control processor, 39J, transmits a message that consists of binary information of a "00" header (indicating a command with execution and meter-monitor segments) then the execution segment information of the pseudo command then a meter-monitor segment containing said monitor information in RAM (including the associated channel mark and the format information of said information) then any padding bits required to end said message. (Hereinafter, said message whose transmission is caused by receiving said first command is called the "1st-old-program-command (#5).") Then, in a predetermined fashion, control processor, 39J, determines that said first command contains subject matter meter-monitor information causing said control processor, 39J, to transmit a message that consists of binary information of a "00" header then particular execution segment information that is addressed to microcomputer, 205, (and that causes microcomputer, 205, to process the information of the meter-monitor segment immediately following said execution segment information as new programming now being transmitted on the channel of the channel mark of said meter-monitor segment) then meter-monitor segment information that includes the "program unit identification code" and subject matter information of said first command and the channel mark of cable channel 13 as well as appropriate meter-monitor format information then any padding bits required to end said message. (Said message whose transmission is caused by receiving said first command enables microcomputer, 205, in a fashion described more fully below, to tune automatically to receive the program that said "program unit identification code" identifies if said program is of interest, and said

253

message is called, hereinafter, the "1st-new-program-message (#5)".) Then said control processor, 39J, deletes from said RAM all information of said monitor information in RAM except the information of said channel mark and records at said RAM, 5 associated with said channel mark, the meter-monitor segment information of the information at said SPAM-input-signal memory, which is said first command, but replaces the meter-monitor format information that is recorded with new format information that reflects the addition of a channel mark. 10 Finally, controller, 39J, transmits particular detection-complete information to controller, 20; causes all apparatus of decoder, 30, except said RAM to cease receiving SPAM message information and delete all information received on said frequency of interest (that is, cable channel 13); and 15 causes said matrix switch, 39I, to cease transferring information from said control processor, 39J, to said buffer/comparator, 8, and commence transferring SPAM message information from EOFs valve, 39F, to its null output.

Receiving said detection-complete information causes 20 controller, 20, to cause oscillator, 6, to cause the selection of the next channel in the predetermined television channel selection pattern: wireless channel 5. Automatically oscillator, 6, causes switch, 1, to shift its contact lever from the first alternate contact to the second alternate 25 contact to which wireless transmissions are inputted and causes mixer, 3, to select the frequency of channel 5 and input said frequency of interest, at a fixed frequency, to decoder, 30. Controller, 20, then transmits a particular preprogrammed wireless-5 instruction to said control 30 processor, 39J, that informs said processor, 39J, wireless channel 5 is inputted to decoder, 30.

Receiving said wireless-5 instruction causes control 35 processor, 39J, to cause all apparatus of decoder, 30, to commence receiving, detecting, and processing SPAM message information embedded in the inputted frequency of interest.

254

When the input of wireless channel 5 to decoder, 30, commences, the remote wireless station transmitting the channel 5 transmission is transmitting the embedded signal information of an information segment following a SPAM 5 command. Shortly thereafter, embedded signal information of an end of file signal then a combining synch command with a "01" header is transmitted on wireless channel 5. Said command instructs ITS controller/computers, such as 73 in Fig. 6 (except that the intermediate transmission station of 10 this transmission is a wireless transmission station rather than a cable station), to load and run the contents of the information segment following said command. The meter-monitor field of said command contains no subject matter information but identifies a particular super market chain 15 commercial program unit.

Receiving the inputted frequency of interest of wireless channel 5 at decoder, 30, causes filter, 31, to filters the inputted fixed frequency and output the one TV channel signal of channel 5 to amplitude demodulator, 32; 20 causing demodulator, 32, to demodulate said inputted channel signal and transfer the demodulated signal to line receiver, 33; causing line receiver, 33, to detect said embedded signal information and transmit it to digital detector, 34; causing digital detector, 34, to detect the binary information of 25 said signal information and transfer said binary information to controller, 39. Receiving said binary information at controller, 39, causes the binary SPAM information of the wireless channel 5 transmission to be checked and corrected, as necessary, at processor, 39B; converted into locally 30 usable binary information at processor, 39D; and checked for end of file signal information at EOFs valve, 39F, and transmitted to the null output of matrix switch, 39I, until EOFs valve, 39F, detects an end of file signal.

In due course, said EOFs valve, 39F, receives the 35 aforementioned end of file signal causing said valve, 39F, to

255

detect said signal and transmit the aforementioned interrupt signal of EOFs-signal-detected information to said control processor, 39J. Receiving said EOFs-signal-detected information causes control processor, 39J, to transmit the  
5 aforementioned discard-and-wait instruction to EOFs valve, 39F, and to cause said matrix switch, 39I, to cease transferring SPAM message information from said EOFs valve, 39F, to its null output information and commence transferring SPAM message information from said valve, 39F, to said  
10 control processor, 39J. Receiving said instruction causes said valve, 39F, to set the information at the EOFs WORD Counter of said valve, 39F, to "00000000" (thereby discarding information of said end of file signal) and to transmit the aforementioned complete-and-waiting information to control  
15 processor, 39J, as an interrupt signal. Receiving said complete-and-waiting information causes control processor, 39J, to transmit the aforementioned reopen-flow instructions to EOFs valve, 39F, causing said valve, 39F, to recommence processing inputted signal words in its preprogrammed fashion  
20 and transferring said words to matrix switch, 39I, and control processor, 39J, commences waiting to receive from said valve the binary information of a subsequent SPAM header.

The command that then follows on wireless channel 5  
25 contains one example of an execution segment that invokes no controlled functions at the station of Fig. 3. Said command is addressed to intermediate transmission station controller/computers. Its instructions control, among others, the controller/computer of the remote station  
30 transmitting the wireless channel 5 transmission. (Fig. 6 shows one example of such a controller/computer, 73.) The subscriber station of Fig. 3 is an ultimate subscriber station, and the commands that invoke controlled functions at the computer of the station of Fig. 3 are those that are  
35 addressed to URS microcomputers, 205.
